## THE INFLUENCE OF SODIUM BENZOATE ON THE NUTRITION AND HEALTH OF MAN.

## REPORT OF THE REFEREE BOARD OF CONSULTING SCIENTIFIC EXPERTS.

Of the questions referred to this board a the first to engage our attention have been the following:

- (1) "Does a food to which there has been added benzoic acid, or any of its salts, contain any added poisonous or other added deleterious ingredient which may render the said food injurious to health? (a) In large quantities? (b) In small quantities?"
- (2) "If benzoic acid or any of its salts be mixed or packed with a food, is the quality or strength of said food thereby reduced, lowered, or injuriously affected? (a) In large quantities? (b) In small quantities?"

To obtain satisfactory answers to these questions, the board has felt it necessary to carry through a careful investigation of the effect of benzoic acid or some one of its salts on the nutrition and general health of man. A thorough study of the literature giving the results of work done by various investigators on the physiological effects of benzoic acid and its salts, together with a study of reported clinical and medical observations, therapeutic usage, etc., have made it apparent that additional work was needed to render possible a conclusive answer to the above questions.

With a view to limiting the scope of the work, while at the same time meeting all practical requirements, our investigation, with the consent of the Secretary of Agriculture, has been confined to a study of the effect of the sodium salt of benzoic acid, viz, sodium benzoate.

To make this experimental inquiry as thorough as possible and to minimize the personal equation, three independent investigations

<sup>&</sup>lt;sup>a</sup> Dr. Alonzo E. Taylor, professor in the University of California, a member of this board, owing to absence in Europe, has not been able to participate in the investigations embodied in this report.

have been carried out; one at the Medical School of Northwestern University in Chicago, under the charge of Prof. John H. Long, of that institution; a second at the private laboratory of Prof. Christian A. Herter, of Columbia University, New York City; and the third at the Sheffield Scientific School of Yale University, in charge of Prof. Russell H. Chittenden.

The same general plan of procedure was followed in all three experiments. A certain number of healthy young men were selected as subjects, and during a period of four months these men, under definite conditions of diet, etc., with and without sodium benzoate, were subjected to thorough clinical and medical observation, while the daily food and the excretions were carefully analyzed, and otherwise studied, and comparison made of the clinical, chemical, bacteriological, and other data collected. (For details see the individual reports.) In this manner material has been brought together which makes possible conclusious regarding the effect of small and large doses of sodium benzoate upon the human system.

In fixing upon the amount of sodium benzoate that should constitute a "small dose" we have adopted 0.3 gram of the salt per day. Manufacturers of food products which in their view require the use of a preservative are in general content with 0.1 per cent of sodium benzoate. This would mean that in the eating of such a preserved food the consumer would need to take 300 grams per day, or nearly two-thirds of a pound, of preserved food to ingest an amount of benzoate equal to our minimal daily dosage. Looked at from this point of view, our dosage of 0.3 gram per day seemed a fair amount for a "small dose," one that would clearly suffice to show any effect that small doses of the salt might exert, especially if continued for a considerable length of time. In all these three experiments this daily dosage was continued for a period of about two months. Under "large dose" was included quantities of sodium benzoate ranging from 0.6 gram to 4 grams per day. Such a daily dosage was continued for a period of one month. In a few instances somewhat larger doses were employed.

As the amount and character of the daily diet exert a well-known influence upon many of the metabolic or nutritive changes of the body, as well as upon the bacterial flora of the intestines, attention is called to the fact that the three investigations differed from each other in the amount of protein food consumed daily, thereby intro-

ducing a distinctive feature which tends to broaden the conditions under which the experiments were conducted.

The conclusions reached as a result of the individual investigations are given at length in the separate reports herewith presented, together with all of the data upon which these conclusions are based.

The fact should be emphasized that the results obtained from the three separate investigations are in close agreement in all essential features.

The main general conclusions reached by the referee board are as follows:

- (1) Sodium benzoate in small doses (under 0.5 gram per day) mixed with the food is without deleterious or poisonous action and is not injurious to health.
- (2) Sodium benzoate in large doses (up to 4 grams per day) mixed with the food has not been found to exert any deleterious effect on the general health, nor to act as a poison in the general acceptation of the term. In some directions there were slight modifications in certain physiological processes, the exact significance of which modifications is not known.
- (3) The admixture of sodium benzoate with food in small or large doses has not been found to injuriously affect or impair the quality or nutritive value of such food.

# AN EXPERIMENTAL STUDY OF THE INFLUENCE OF SODIUM BENZOATE ON THE NUTRITION AND HEALTH OF MAN.

By Russell H. Chittenden.

#### INTRODUCTORY.

In an attempt to answer the questions, "Does a food to which there has been added benzoic acid, or any of its salts, contain any added poisonous or other added deleterious ingredient which may render the said food injurious to health; in large quantities; in small quantities?" the following experimental work has been performed, with results which seemingly afford positive answers to the above questions.

With a view to limiting the scope of the work, while at the same time meeting all practical requirements, and with the consent of the Secretary of Agriculture, our investigation has been confined to a study of the sodium salt of benzoic acid, viz, sodium benzoate.

The work has been carried on in the laboratories of the Sheffield Scientific School of Yale University under the personal supervision of the writer. The chemical work was under the special charge of Frank P. Underhill, Ph. D., assistant professor of physiological chemistry in the Sheffield Scientific School, with a suitable corps of trained chemists and assistants. The bacteriological work was in charge of Leo F. Rettger, Ph. D., assistant professor of bacteriology and hygiene in the Sheffield Scientific School, while the necessary medical and clinical examinations were made by Richard F. Rand, M. D., elinical assistant at the Yale Medical School.

The subjects—six in number—on whom the effects of sodium benzoate were to be studied were carefully selected with a view to obtaining different types of physical and mental make-up, as well as persons of well-known character and responsibility. All of the subjects chosen were graduate students in the university, thoroughly trained in chemistry and physiology, so that they were able to serve not only as subjects in the experiment, but likewise as analysts, capable of assisting in the gathering of the data. All were known to the writer for several years.

The experiment was commenced the 1st of July and extended to the 8th of November. During this period of four months the subjects were fed at a private table provided nearby the laboratory, where complete supervision could be had of the amount and character of the food taken, with all facilities for weighing the food consumed by each subject, preparation of suitable samples of the various foods for chemical analysis, etc.

#### PLAN OF THE EXPERIMENT.

For a week prior to the actual commencement of the experiment the subjects were required to take their meals at the table provided; the urine and feces were collected daily; partial analyses made, sufficient to indicate the general extent of their body metabolism; the amount of food consumed daily by each individual noted; clinical and medical examinations made, etc., with the purpose of obtaining a general view of the physiological characteristics or personal peculiarities of the individual subjects.

The experiment proper was divided into a fore period of 2 weeks or 14 days, i.e., from July 6 to July 19, inclusive, in which complete daily records were made of the subjects under normal conditions of life and diet. This was followed by a benzoate period of 2 months, from July 20 to September 20, inclusive, in which each subject was fed with his food daily 0.3 gram of sodium benzoate. This constituted the "small dose," and being continued over a period of 62 days would seemingly provide ample opportunity for the detection of any effects which small doses of sodium benzoate might produce. In this connection it is to be noted that during this period of 2 months each subject took 18.6 grams of sodium benzoate. Next followed an "after period" of 10 days, from September 21 to September 30, inclusive, in which no benzoate was given, thus affording another so-called normal period for comparison. For the next 4 weeks, commencing with October 1, larger doses of sodium benzoate were given as follows: During the first week, from October 1 to October 7, inclusive, the daily dose was 0.6 gram; for the week October 8 to 14, inclusive, the dose was increased to 1 gram daily; from October 15 to 21, inclusive, 2 grams of sodium benzoate were taken daily by each subject; on October 22 the dosage of benzoate was increased to 4 grams per day, at which level it was continued for the following 7 days. During this period of "large doses" of sodium benzoate, covering 28 days, each subject took a total of 53.2 grams of benzoate. Finally, there was another "after period" of 10 daysfrom October 29 to November 7, inclusive—in which no benzoate was given. All through the period of 125 days covered by the experiment, accurate data were collected of food consumption, food composition, urine excretion, fecal discharges, for each subject, together with chemical composition of the daily excretions, etc., reinforced by the clinical and medical examinations, bacteriological examinations of feces, blood count, etc. In this way competent comparison of the condition or conditions produced by small and

large doses of sodium benzoate, with the normal condition of the same subjects, might be expected, and thus light be thrown upon the effects of sodium benzoate on healthy individuals.

#### ADMINISTRATION OF THE SODIUM BENZOATE.

In the administration of the benzoate an attempt was made to imitate the manner in which the salt would be taken if used in food as a preservative. With the smaller dose of 0.3 gram per day, the salt was dissolved in a given amount of water and then added to some one food so that the latter would contain one-tenth of 1 per cent of sodium benzoate. The salt was given three times a day-0.1 gram of benzoate with each meal—and in some one article of food, where it would be present to the extent of about one-tenth of 1 per cent by weight of that food. In this way was avoided any possible local effect of a relatively large single dose, as might perhaps happen if administered by capsule. Further, this method of administration insured entrance into the stomach of essentially the same percentage of benzoate, even when the dosage was increased to 0.6 gram per day. With larger doses of sodium benzoate the same general method of procedure was followed, though with a daily dosage of 2 grams and over the amount of benzoate in the food rose necessarily above 0.1 per cent.

A word of explanation may be offered here regarding the size of the "small dose" of sodium benzoate employed in our experiment. In adopting 0.3 gram of the salt as the daily dose we were influenced by the bearing of our problem upon the practical question of the use of sodium benzoate as a food preservative. Manufacturers of food products requiring the use of a preservative are apparently content with an allowance of 0.1 per cent of sodium benzoate. The consumer of such a product would need to take 300 grams—nearly two-thirds of a pound—of such a preserved food per day to ingest an amount of sodium benzoate equal to our minimal daily dosage. In other words, looked at from this standpoint, our dosage of 0.3 gram per day seemed a fair amount for a "small dose," one that would clearly suffice to show any effect that small doses of the salt might exert, especially if continued for a reasonable length of time.

In this connection it is interesting to note the relationship between the ingested sodium benzoate and the total food consumption of our different subjects per day during the several benzoate periods. The following table, giving the total amount of food consumed per day, together with the dosage of benzoate, shows the percentage of benzoate in the total day's food of the six subjects. From these

<sup>&</sup>lt;sup>a</sup> The sodium benzoate employed was "soda benzoate," U. S. P., 99 per cent. It contained a trace of calcium and 2.2 per cent of water. In giving the salt, allowance was made for 99 per cent pure and the contained water, so that the daily doses specified represent actual sodium benzoate.

figures it is seen that with a daily dose of 0.3 gram of benzoate, the percentage of the salt in the total food consumed varied from 0.015 to 0.022 per cent. With a dosage of 0.6 gram per day the proportion of benzoate in the day's food varied from 0.032 per cent to 0.04 per cent. When 1 gram of sodium benzoate was taken daily the proportion of salt to the total food consumption varied from 0.055 per cent to 0.069 per cent. With a dosage of 2 grams per day, the total food consumed showed 0.108 to 0.13 per cent of sodium benzoate; while with a daily dose of 4 grams the proportion of benzoate to the total food consumption per day varied from 0.25 per cent to 0.31 per cent.

Percentages of sodium benzoate in the total day's food.

#### CHARACTER OF THE DAILY DIET.

In any study of nutritive changes, especially such as extend over long periods of time, the character and amount of the daily diet are important factors. In our experiment two facts are to be empha-First, the subjects were not restricted to a limited dietary, but on the contrary were allowed reasonable freedom of choice, both as to character and quantity of the daily food. In other words, there was no interference with the normal desires of the individual, but each subject was allowed full latitude in the exercise of his personal likes and dislikes. To be sure, each day a definite menu was arranged for all three meals, but this was sufficiently generous in character to admit of choice; further, after a short time sufficient knowledge was acquired of the special tastes of the subjects, so that a daily dietary could easily be provided quite satisfactory to all. By this method of procedure there was no violation of that physiological good sense so essential in experiments of this character. Second, after the first few weeks the subjects, consciously or unconsciously. settled down to a relatively low protein diet, which was maintained throughout the experiment. This is a point to be emphasized, since as protein metabolism is influenced largely by the intake of protein food we had in our experiment a definite condition; one which afforded an opportunity for the study of the effect of sodium benzoate upon subjects living under a relatively low protein intake and consequently at a somewhat lower level of nitrogen metabolism than is ordinarily maintained by the majority of mankind. The following table shows the average daily intake of nitrogen for each subject during the five periods of the experiment:

#### Daily average intake of nitrogen.

Date.	н. н. с.	W.W.H.	L. M. L.	J. F. L.	Е. С. М.	W. C. R.
July 6 to 19 July 20 to September 20 September 21 to 30 October 1 to 28 October 29 to November 7	11.64	Grams. 13.50 11.52 11.32 11.94 11.41	Grams. 15. 28 12. 65 12. 39 12. 69 13. 23	Grams, 13.71 13.12 12.63 11.90 13.08	Grams. 14.02 12.77 12 28 12.13 12.88	Grams. 11. 56 11. 08 11. 18 11. 37 11. 29

The results are certainly suggestive as showing how individuals tend to maintain within reasonable limits a definite average nitrogen intake, even though entirely unhampered by restrictions as to quality of food or quantity. The larger intake of nitrogen during the first period of 2 weeks, noticeable in 4 of the subjects particularly, was due without doubt to the stimulating effect of the change to the new table. Both the menu and the cooking of the experimental table were excellent, and a general change of living such as was involved

here might well serve as a temporary stimulus to appetite. (For details regarding the daily food of the several subjects and the content of nitrogen in the same, see appended tables of food composition, p. 221.)

While the nitrogen intake of our subjects was relatively low, the fuel value of the daily food was not essentially different from the values usually seen. In other words, the daily intake of fats and carbohydrates was such that the heat-giving power of the food averaged about 3,000 large calories per day. While these data are not based wholly upon accurate chemical analysis, as in the determination of the nitrogen of the food, they are sufficiently near the truth to have value in showing the general character of the daily dietary as looked at from the standpoint of energy-yielding power. The following table gives a sufficient number of data to indicate the average values for each subject:

Estimated fuel value of the daily food.

#### CLINICAL OBSERVATIONS.

#### SUBJECT No. 1-H. H. G.

This subject was a young man, 24 years of age, an assistant in the chemical laboratory. At the initial examination, made by the medical inspector July 2, 1908, he was described as of slender build, weighing 50.8 kilograms; skin pale; mucous membranes of fair color; "adenoid face" (mouth breather) with high palatal arch. His chest was long, narrow, and flat. Lungs were normal, breath sounds and resonance being of normal character; complete absence of râles or dullness. The heart sounds were clear; the point of maximum impulse was visible in the fifth interspace inside of the nipple line. The abdomen was flat, with normal respiratory movements, soft on palpation, no mass felt. The spleen and kidneys were not palpable. Liver dullness was normal. Knee jerk weak. Body temperature

was 98.6°. Pulse, 78 beats per minute and quite regular, with fair volume and tension. The urine was of a pale yellow color, slightly cloudy. The small sediment which eventually separated was composed of amorphous phosphate. The reaction of the urine was acid. Specific gravity, 1.016. The urine was free from albumin, sugar, and bile. Careful microscopic examination of the slight sediment showed an absence of tubular casts, cells, etc. The only noticeable component of the sediment was the amorphous phosphate already referred to, with a few crystals of dicalcium phosphate and a few mucous threads.

On July 14 the subject had a "cold." There was slight follicular tonsilitis and pharyngitis. His temperature was 99°; pulse, 88. An antiseptic gargle was prescribed and calomel given. In three days the patient was quite well.

On July 29 clinical examination showed the heart, lungs, and abdomen normal. General condition wholly unchanged. Subject stated that he felt well. Body temperature was 98°. Pulse beat 66 per minute. The urine had a specific gravity of 1.018; was very faintly acid in reaction; pale yellow in color, and showed a slight white precipitate of amorphous phosphate. There were no casts, cells, or other substances of pathological significance. Tests of the urine made for albumin, sugar, etc., were wholly negative.

On August 4 the subject was treated for laceration of hand caused by the breaking of glass apparatus in the laboratory. There were two punctured wounds over lower and second metacarpal at the base of the index finger. There was loss of sensation along the outer side of finger. The wounds were dressed on August 4, 6, 8, and 12. On the latter date the wounds had healed per primary; loss of sensation still persisted. It was thought advisable to wait and see if sensation would return before doing exploratory operation for nerve suture, as the subject was anxious to keep on with his work.

On September 1 clinical examination showed no deviation from the normal.

On September 24, near the close of the first benzoate period, another examination showed body temperature 98.8°; pulse, 82 beats per minute; regular, with fair volume and tension. The urine was free from any casts or cells. A few mucous threads were observed, and a few crystals of calcium oxalate with some amorphous phosphate. The heart, lungs, and abdomen were normal. The general condition of the subject was good. He was gaining in weight and felt quite well.

On October 14, after a week of taking 1 gram of sodium benzoate per day, the body temperature was found to be 98°; pulse, 70 beats per minute; regular, with good volume and tension. The heart, lungs, and abdomen were normal; general condition excellent. Subject stated that he felt very well. The urine was entirely normal.

On October 22, at the close of the week when 2 grams of sodium benzoate had been taken daily, the same general condition of good health prevailed, with no deviation from the normal.

On October 28, at the close of the week when 4 grams of sodium benzoate had been taken daily, the body temperature was found to be 98.2°; pulse, 74 beats per minute; regular, and with good volume and tension. The heart, lungs, and abdomen were normal. General condition was good, the subject stating that he felt well, with continued gain in body weight. The urine was perfectly normal, free from casts or any other abnormality.

On November 7, at the close of the final after period, clinical examination showed body temperature 98°; pulse, 76 beats per minute; with good volume and tension. The heart, lungs, abdomen, liver, and spleen were normal. No changes in the physical condition of the subject could be observed during the course of the test. Subject stated that he felt well and had noticed no change in his health one way or the other during the period of the experiment. He had gained 6 to 7 pounds in body weight. The urine was normal and free from sediment, except a few mucous threads. Careful questioning of the subject with regard to his impressions as to possible action on the part of the sodium benzoate led to negative statements, with the exception that during the larger dosage of sodium benzoate he thought the bad taste of the salt objectionable.

#### SUBJECT No. 2-W. W. H.

This subject was a young man, 24 years of age, with a body weight of 51.6 kilograms. He was small and slight. The first clinical examination, made July 6, showed the following: Skin and mucous membranes of good color; partial mouth breather, nasal obstruction due to septal deformity. The chest was fairly well formed; rather long, flat, and narrow. Lungs were normal; breath sounds and resonance normal. The heart sounds were clear; the point of maximum impulse was visible in the sixth interspace inside of the nipple line. The abdomen was full, soft, normal tympany, no mass. Spleen and kidneys were not palpable. Liver in normal position. Body temperature, 98.4°. Pulse, 70 beats per minute; regular, with good volume and tension. The urine was pale yellow in color, slightly cloudy; acid reaction; specific gravity 1.016. The slight sediment in the urine was composed of amorphous phosphate. No casts; no cells. Tests for albumin, sugar, bile, etc., were wholly negative. On July 29 the heart, lungs, and abdomen were found normal. General physical condition of the subject was good. Body temperature was 98°; pulse, 69 beats per minute.

On August 5 the subject had a sore throat; coryza, pharyngitis, and a few "spots" on the left tonsil. Necessary treatment was given.

Body temperature was 101.2°; pulse, 87 beats per minute. On August 7 his throat was practically normal. August 24 there was a slight recurrence of sore throat. The pharyngitis, however, was very slight and quickly alleviated by an antiseptic gargle.

September 5 the general condition was good; no deviation from the normal in body temperature, pulse rate, or in the character of the

urine.

September 25 the body temperature was 98.2°; pulse beat, 74; regular, with fair volume and tension. The heart, lungs, and abdomen were normal. General physical condition good, with some increase in body weight. The urine had a specific gravity of 1.018, and was free from albumin, sugar, or any abnormal substance. Microscopic examination of the slight sediment showed a few mucous threads and crystals of calcium oxalate. No casts were to be found.

October 13 the body weight still showed increase. The heart, lungs, and abdomen were normal. General physical condition was good, the subject stating that he felt perfectly well. Body temperature was 98°; pulse, 78; regular, with good volume and tension.

On October 20, when the subject was taking 2 grams of sodium benzoate per day, examination showed the same good physical condition, with complete absence of any signs of abnormality in the urine.

October 27, near the close of the largest benzoate dosage, clinical examination showed the heart and lungs normal; abdomen full and soft; rather more gas in the intestines than in previous examinations. Subject stated that he had had slight gastro-intestinal fermentation for two days. Subject stated that he felt well and his general physical condition was plainly good. His body weight was increased. Body temperature was 98°; pulse, 78 beats per minute; regular, with good volume and tension. The urine was yellow in color; specific gravity, 1.020; acid in reaction and free from albumin, sugar, etc. A slight cloudy precipitate appeared in the urine on standing. Microscopic examination of this sediment showed a small amount of amorphous phosphate and a few crystals of calcium oxalate. Long search revealed two finely granular casts. There were no cells.

On November 5, near the close of the experiment, final clinical examination showed the heart, lungs, and abdomen normal. Body temperature was 99°; pulse, 78 beats per minute; regular, with good volume and tension. No change was observed in the physical condition of the subject during the entire course of the experiment, with the slight exception noted above. The subject himself stated that he felt as well as at the beginning of the period and that he had seen no ill effects from the test so far as subjective symptoms go. He had gained 6 pounds in body weight, and his general physical condition had plainly improved during the period of the test. Final

examination of the urine showed a specific gravity of 1.018, with freedom from albumin, sugar, and bile, but with a slight sediment which under the microscope was found to be composed of amorphous phosphate, with a few mucous threads and calcium oxalate crystals. No cells were to be found. Repeated examination revealed one finely granular cast.

#### SUBJECT No. 3.-L. M. L.

A graduate student in the university; age, 22 years. Body weight at the beginning of the experiment was 70 kilograms. On July 1 the first clinical examination gave the following results: The subject was of medium size, well nourished, and well muscled. Skin and mucous membranes were of good color. Chest well formed—muscular. The heart sounds were clear, the apex beat at the fifth interspace inside of the nipple line. The lungs showed normal resonance, with normal breath sounds. The abdomen was muscular, full, soft negative; arteries soft. Body temperature, 98.2°; pulse, 82 beats per minute; regular, with good volume and tension. The urine was light yellow in color; acid in reaction; with a specific gravity of 1.016. Tests for albumin, sugar, bile, etc., were negative. The urine showed a slight cloud, which on subsidence was found to be composed of amorphous phosphate. There were no casts; no cells.

July 31 the body temperature was 99°; pulse 95 beats per minute. Nothing abnormal was to be detected in the urine or on physical examination.

September 5, body temperature, 98.8°; pulse, 110 beats per minute; fairly regular, with low volume and tension. The increased pulse rate was due apparently to excess in smoking. The heart sounds were clear. The subject was advised to diminish his smoking. The urine was free from casts, cells, or any abnormal substance. The general physical condition of the subject was excellent.

September 24, the date on which this examination was made, the subject was in a student rush, in which he was for several hours subjected to severe physical strain. This fact is mentioned, since the urine collected this day showed on microscopic examination a few finely granular casts, with some hyaline casts. Body temperature was 98.2°; pulse, 84 beats per minute; fairly regular, with low volume and tension. Aside from these casts in the urine, the examination revealed no suggestive features. The urine was entirely free from albumin and sugar. A microscopic examination of the urine on September 26 showed entire absence of casts. The excessive physical exertion endured by the subject September 24 undoubtedly accounts for the presence of the few casts found in the urine.

October 12 the body temperature was 98.1°; pulse, 94 beats per interpretate; fairly regular, with low volume and tension. Heart, lungs, and pidomen were normal. The general physical condition of the

subject was excellent. There was a gain of 2 pounds in body weight. The urine was clear, entirely free from casts, cells, or other sediment aside from a slight mucous cloud. There was likewise freedom from albumin, sugar, and bile.

October 19, the heart, lungs, and abdomen were normal. General physical condition excellent. Urine clear, with the exception of a slight cloud on standing. This sediment, under the microscope, showed a few crystals of calcium oxalate and several mucous threads. Two finely granular casts were found. On this date the subject was in a vigorous wrestling match, and it is probable that the casts in the urine were due to the severe physical exercise.

October 26, body temperature was 98°; pulse, 98 beats per minute; regular, with fair volume and tension. The urine had a specific gravity of 1.016 and showed on microscopic examination two fine and slightly granular casts. These two casts were found on searching four distinct slides. A few calcium oxalate crystals and some amorphous phosphates were also seen.

November 5, the final examination of this subject showed the heart, lungs, abdomen, liver, and spleen normal. His general physical condition was excellent. Subject stated that he felt no ill effects from the test; had gained in body weight. Aside from the increased heart beat noted under date of September 5, there has been no change in the original physical findings. The subject appeared to be in better condition than at the beginning of the test. His body temperature was 98°, pulse 88 beats per minute, regular, with fair volume and tension. The urine was free from albumin, sugar, bile, etc., and clear on standing. Microscopic examination failed to show any casts or cells. The subject stated that the only effect he experienced in taking the sodium benzoate was a slight feeling of nausea on the days when the larger doses were taken. This he attributed to the smell of the substance, since the nausea, he stated, was not experienced when he took the food containing the benzoate with the nostrils closed.

#### SUBJECT No. 4-J. F. L.

This subject was an assistant in the laboratory, 27 years of age, with a body weight of 67.2 kilograms. At the first examination made on July 9 he was found to be well developed, fairly well nourished, and muscular—a man of the clean, long-limbed, lean type. Skin and mucous membranes were of good color. The chest was broad, rather flat, with a slight depression at the lower end of sternum. The lungs were normal, with good breath sounds and normal resonance. The heart sounds were clear; the point of maximum impulse was visible in the fifth interspace inside of the nipple line. The abdomen was flat, soft, with freedom from masses. The spleen and kidneys were not palpable. Liver to costal margin. The knee

jerk was normal. Body temperature was 98.4°, pulse 70 beats per minute, regular, with good volume and tension. The urine was light yellow in color, clear, with a specific gravity of 1.018, slightly acid reaction. Tests for albumin, sugar, bile, etc., were negative. The urine was free from casts and cells.

July 30 the body temperature was 98.6°, pulse 82 beats per minute, regular, with fair volume and tension. The heart, lungs, and abdomen were normal. General physical condition was excellent. Subject stated that his general health had been fine during the past month. Body weight had increased 5 pounds. Urine was normal, with freedom from casts and cells. A few mucous threads were seen.

September 1, heart, lungs, and abdomen were normal. General condition excellent. Subject stated that his health was fine, but he was slightly constipated. He had gained 4 additional pounds in body weight. Body temperature was 98.2°, pulse 80 beats per minute, regular, with fair volume and tension. The urine was normal in every respect; no casts and no crystalline sediment.

September 23, clinical examination on this date showed the heart, lungs, and abdomen normal. Physical condition excellent. Constipation had disappeared, and subject has daily stools. Feels in excellent health. Body temperature 98.2°, pulse 74 beats per minute, regular, with fair volume and tension. Urine normal, with freedom from casts and cells, and no trace to be found of albumin, sugar, or other abnormal substances.

October 13, body temperature was 98°, pulse 80 beats per minute, regular, with good volume and tension. Heart, lungs, and abdomen were normal. General condition excellent. Had been working overtime in the laboratory and felt a bit tired, otherwise quite well. The urine was normal in every respect.

October 20, no physical examination was made on this date, as the subject appeared in excellent condition. The urine, however, was carefully examined, but no trace of any abnormal constituent was found, neither were there any casts or cells in the slight sediment which eventually developed on standing. A few mucous threads and a few crystals of calcium oxalate only were found.

October 27, near the close of the large doses of sodium benzoate, the subject was subjected to a critical physical examination. Heart, lungs, and abdomen were normal in every respect. The general condition of the subject was excellent. He felt well, had been working very hard for the past few weeks, but with no effect except a slight loss of appetite.

November 6, final examination of this subject showed the heart, lungs, and abdomen normal, liver and spleen not palpable. Body temperature was 98°, pulse 85 beats per minute, regular, with fair volume and tension. The general physical condition was excellent. If

anything, the subject appeared in better condition than at the beginning of the experiment when he was first examined. He had gained 7 to 8 pounds in body weight. No change in the physical condition of the vital organs could be detected. The subject stated that he was not conscious of any ill effect from the benzoate feeding. The subject thought that some little diuresis had been produced as the result of the benzoate. This point, however, will be discussed in connection with data to be presented under the head of "Effect on the composition of the urine." Final examination of the urine showed complete freedom from abnormal components of every kind. There were no casts, no cells. In the slight sediment which appeared in the urine only a few mucous threads were seen.

#### SUBJECT No. 5-E. C. M.

This subject was one of the assistants in the laboratory, 29 years of age, and weighed 67.1 kilograms at the time of the examination, June 29. He was a lean, clean-built man; skin and mucous membranes of good color, except for dark rings under his eyes, which he stated he had had all his life. The heart impulse was palpable at the fifth interspace nipple line; sounds clear at both apex and base; no murmurs. The lungs were healthy, respiratory movements normal, breath sounds faint, but no râles and no dullness. The radial arteries appeared soft, the brachials slightly thickened. The abdomen was flat and soft, with normal tympany. Liver was of normal size, spleen not palpable. No glandular enlargement; no varicose veins. Body temperature was 99°, pulse 68 beats per minute, regular, with fair volume and tension. The urine was pale yellow in color, clear on standing, slightly acid in reaction, and with a specific gravity of 1.014. There were no casts or cells present, neither albumin, sugar, bile, etc.

July 27 the subject had an acute gastro-intestinal attack, with abdominal pain, tenderness, and diarrhea. Body temperature was 99°, pulse 70. This attack was counteracted by calomel, saline, etc. Recovery was complete on July 31.

July 31, body temperature was 98°, pulse 66 beats per minute, regular, with low volume and tension. Heart sounds were faint, slight murmurish quality at apex during inspiration. The subject was given a tonic pill of strychnine 1/40, quinine 1/2, and ferri carb. sacch. The urine was perfectly normal in character and free from sediment. No casts and no cells of any kind were found.

September 25, body temperature was 98°; pulse 69 beats per minute; regular, with fair volume and tension. Heart sounds clear; good quality. General condition of the subject was excellent; had gained two pounds in weight. The urine was free from sugar, albumin, and other abnormal substances. Microscopic examination showed

complete absence of casts, cells, etc. Many mucous threads were found in the slight sediment, together with some crystals of calcium oxalate and some amorphous phosphate.

October 14 the body temperature was 98.4°; pulse 68 beats per minute; regular, with good volume and tension. Physical condition continued good. The urine was entirely free from any abnormality.

October 19, heart, lungs, and abdomen were normal. General condition was good. Urine tests for abnormal substances were all negative. No casts and no crystals of any kind were to be found.

October 26, careful physical examination of the subject showed no change from the original findings as to heart, lungs, liver, spleen, abdomen, etc. The urine was normal, and there were no casts or cells present.

November 6: The final examination of the subject was made on this date. Body temperature was 98.4°; pulse 70 beats per minute; regular, with good volume and tension. The general appearance of the subject was good; he seemed in better health than on June 29. Heart, liver, abdomen, skin, and mucous membranes were normal, except for rings under the eyes. Subject stated that he felt very well and had noticed no change in health or feeling as a result of the benzoate feeding. He had lost 2 pounds in weight during the last month, which he attributed to extra work, as he had been doing night work in addition to his daily routine. Final examination of the urine showed complete freedom from abnormal substances, with no trace of casts or sediment.

#### SUBJECT No. 6-W. C. R.

This subject, a graduate student in the university, weighed at the beginning of the experiment 58.8 kilograms. He was 21 years of age; of slender build, with slight muscular development. Skin and mucous membranes were of fair color. On June 29 his body temperature was 98.8°; pulse 96 beats per minute; low volume and tension. The rhythm varied slightly. Chest was symmetrical; flat, with good expansion. Breath sounds were clear; no râles and no dullness. The heart apex beat was visible at the fifth interspace nipple line; sounds clear and forceful at both apex and base. Abdomen was flat, soft, negative. Liver and spleen not enlarged. The subject had had typhoid fever ten years ago; was not at all robust in appearance. Urine was pale vellow in color, slightly acid, with a specific gravity of 1.016. Tested for albumin, sugar, bile, etc., with negative results. A slight sediment showed on standing, which under the microscope was found to consist of amorphous phosphate with a little granular matter. There were no casts and no cells.

July 30, general physical condition unchanged. Heart, lungs, and abdomen were perfectly normal. Body temperature was 99°; pulse 98 beats per minute; regular, with low volume and tension. Subject stated that he felt in excellent condition. Urine was wholly free from abnormalities. A few mucous threads were seen in the slight sediment, but no casts or cells.

August 31, on this date the subject had a slight attack of diarrhea; general abdominal pain, with gas in the intestines; headache for thirty hours. The abdomen was found full and soft; slightly tender over the left rectus; dull over colon on left side. Treatment consisted simply of Scidlitz powders, with the result that the subject was perfectly well in thirty-six hours. Body temperature was 98.4°; pulse 82 beats per minute; regular, with good volume and tension. Urine was entirely normal. No casts or cells present.

September 23, heart, lungs, and abdomen were normal. General physical condition was excellent. Subject said that he felt very well. Body weight had increased 2 pounds. Body temperature 98.8°; pulse 81; regular, with good volume and tension. Urine was free from abnormal substances. No casts; no cells; a few crystals of calcium oxalate and amorphous phosphate were present.

October 12, body temperature was 98°; pulse 70 beats per minute; regular, with low volume and tension. The heart sounds were perhaps a little less forceful, with a slightly murmurish quality to the first sound at apex. Apex beat was in the fifth interspace nipple line. No enlargement. Subject stated that he felt perfectly well. The urine was normal.

October 22, pulse 82 beats per minute; regular, with fair volume and tension. Slight murmurish quality to the first sound at apex. Physical findings were otherwise normal and unchanged. Subject felt well. Urine was free from sugar, albumin, etc. No casts or cells present. A few mucous threads and a few crystals of calcium oxalate were found, together with some amorphous phosphate.

October 28, body temperature was 98.2°; pulse 82 beats per minute; regular, with fair volume and tension.

November 7, heart, lungs, abdomen, etc., showed no changes from the original findings. Subject appeared to be in better general health than at the beginning of the test. Body temperature was 98.3°; pulse 83 beats per minute; regular, of good volume and tension. The urine was free from albumin, sugar, bile, etc. The slight sediment showed a few calcium oxalate crystals and some mucous threads. There were no casts or cells. The subject had suffered from slight indigestion and constipation since the benzoate feeding was discontinued. The heart sounds were clear and the lungs clear. Abdomen full, soft; normal tympany, except for dullness over sigmoid. The subject stated that he felt perfectly well.

#### CONCLUSIONS.

The foregoing clinical observations have been taken almost verbatim from the report of the medical examiner. His conclusions are summed up in the following statement:

NEW HAVEN, CONN., December 1, 1908.

Prof. R. H. CHITTENDEN.

Dear Sir: In accordance with your request I examined the sodium benzoate subjects at the beginning of the test, at intervals during the course of the test, and after the benzoate feeding was discontinued. The results of my examinations are recorded in my detailed report.

In general there has been no clinical evidence at any time that the health of the men was at all impaired by the benzoate feeding; on the contrary the men appear to be in better general condition at the conclusion of the test than they were at the start. None of the men have lost in weight, while four have made appreciable gains. Very respectfully yours,

RICHARD F. RAND, M. D.

A general survey of the clinical history of these subjects as recorded fails to show any specific action on the part of the sodium benzoate. There are, however, two or three statements that perhaps need a word of explanation. Subject W. W. H. on October 27 had a slight attack of gastro-intestinal fermentation which lasted two days. This happens to be at the close of the second benzoate period when a dosage of 4 grams per day was being taken. Again, E. C. M. on July 27, viz, at the beginning of the first benzoate period, had a slight gastro-intestinal attack. Further, W. C. R. on August 31, near the close of the first benzoate period, had a brief attack of diarrhea. It might be said that these slight disturbances of the gastro-intestinal tract were due to the benzoate. It is possible that this was the case. It is to be remembered, however, that this experiment was carried out during the hot weather of a New England summer, in a season which was unusually dry and warm. It is not at all strange if three of the subjects should have had for a day or two a slight disturbance such as is recorded above. Certainly, if the slight gastro-intestinal attack suffered by E. C. M. on July 27 was due to the action of sodium benzoate, it would naturally be expected that as the dosage was continued through the following weeks and succeeded by still larger doses in October, there would be a recurrence of these symptoms. On the contrary, the subject had this brief attack for a day or two in July and was not visited by corresponding symptoms at any later date. Further, in the case of W. C. R. the slight diarrhea which occurred August 31, if due to sodium benzoate, would naturally be expected to recur as the dosage was continued and enlarged. Further symptoms of this trouble, however, failed to appear even when the dosage was increased to the maximum of 4 grams per day. It seems far more reasonable to believe that these were incidents such as, especially in the summer time, are liable to occur in the case of any normal individual.

Reference should also be made to the case of L. M. L., whose urine on September 24, October 19 and 26, showed a few granular casts. The conclusion of the medical examiner that the appearance of these casts in the urine was due entirely to physical strain which the subject experienced on those dates seems justifiable. Certainly, if sodium benzoate was the cause, it is singular that no one of the other subjects showed similar signs. Furthermore, it is to be noted that the first appearance of the casts, viz, on September 24, was during the first after period when no sodium benzoate was being taken. Finally, emphasis is to be laid on the fact that at the close of the experiment on November 7 the urine of this subject was entirely free from casts. If sodium benzoate was responsible for the appearance of these few casts in the urine, it would naturally be expected that the deranged condition produced thereby with so large a dosage of benzoate would continue for at least a week or two after cessation of the dosage.

The clinical evidence in all six cases, weighed as carefully as possible, leads to the general conclusion that the health of the subjects was not at all impaired by the sodium benzoate fed. It is proper to add that the general better condition of the subjects as reported by the medical examiner at the conclusion of the test might well be attributed in large measure to the regular mode of life entailed by an experiment of this character.

#### EFFECT ON BODY WEIGHT.

The subjects were weighed at the same hour in the morning every third or fourth day throughout the entire period of the experiment. The record is shown in the following table for all six subjects. For convenience and for the purpose of obtaining a clearer view of the changes in body weight a second table is added, giving the mean body weight of each subject during given periods of seven to ten days. This second table shows the body weight of each subject during the fore period from July 6 to July 19, and then weekly during the first benzoate period, etc.:

Record of body weight.

Comparison of the figures shows that all of the subjects had at the close of the experiment a greater body weight than at the beginning. The gain in weight was quite appreciable in most instances. Reference should be made to one fact which stands out quite notice-

ably when the figures are carefully scrutinized. During the last portion of the experiment, viz, about the middle of October, there was a tendency for body weight to diminish somewhat. In this connection it should be stated that the college year commenced the last of September, so that during the last month of the experiment all of these men had a certain amount of extra work to do. This necessitated their working in the laboratory every night, so that there was an added strain which did not exist during the months of July, August, and September. It is natural to suppose that this added pressure of work may have had an influence both upon appetite and upon body weight. In any event, the fact should be given due emphasis. Examination of the data for the individual subjects shows that H. H. G. began the experiment with a body weight of 51 kilograms and reached a maximum of 54.6 kilograms during the week of September 21, after which he lost somewhat in weight. ending the experiment, however, with a body weight of 53.9 kilograms. W. W. H. began with a body weight of 51.3 kilograms and ended with a body weight of 54.5 kilograms. L. M. L. began the experiment with a body weight of 69 kilograms, and ended with a body weight of 70.8 kilograms. It is perfectly obvious, therefore, that sodium benzoate taken in the doses indicated did not lead to a loss of body weight.

Since body weight—everything else being equal—is closely connected with the daily diet, it is pertinent to remark that the quantity of food taken by these subjects did not increase with the progress of the experiment. Reference to the statements made under the head "Character of daily diet" shows that in every instance less nitrogenous food was ingested daily by all of the subjects during the last half of the experiment than was taken at the outset. Further, the fuel value of the food during the week October 8 to 14 was not essentially different from the fuel value of the food taken near the beginning of the experiment. The increase in the body weight of the subjects, therefore, must be credited, not to any excessive intake of food, but simply to a good nutritive condition, which was certainly not impaired by the sodium benzoate taken with the food.

## EFFECT ON THE BLOOD.

Study of the blood was limited to a determination of the number of red corpuscles (erythrocytes), white corpuscles (leucocytes), and the hemoglobin-content of the blood during the different periods of the experiment; the object of this series of observations being to ascertain whether or no sodium benzoate exerts any noticeable influence upon the formed elements of the blood.

The blood was taken from the tip of the finger or the ear by means of a small lancet. The Thoma-Zeiss counting apparatus was employed

for the enumeration of the red and white corpuscles, while the hemoglobin was determined by the Fleischl hemometer.<sup>a</sup>

First after period: Sept. 28 to Oct. 1 Second benzoate period:	79	85	87	85	79	79
Oct. 14 to 16	79	85	81	80	83	81
period: Oct. 29 to Nov. 3	78	82	86	87	88	83
Final after period: Nov. 6 to 9	80	88	83	90	85	83

Critical study of these results from all sides fails to show any decisive effect, especially when due consideration is given to the well-known fact that the counting of blood corpuscles is always attended with some uncertainty, owing to the necessarily large magnification of small errors of observation.

a In the enumeration of the corpuscles, all the squares on the slide were counted, namely, 144 in the case of the leucocytes and 256 for the erythrocytes, and the averages determined. Further, in most cases counts were made from two samples of blood.

In the estimation of the hemoglobin the results given are the averages of several readings on the color scale, made usually by two observers.

Considering first the erythrocytes, or red corpuscles, the figures show a numerical increase in the number of erythrocytes during those periods when the benzoate was taken and in the periods shortly thereafter in several of the subjects. This is certainly the case with the subjects H. H. G., W. W. H., and W. C. R. The difference, however, between the figures during these periods as compared with the fore period is not great. With the subject L. M. L. there was no great increase during the period of the benzoate feeding. In fact, during the second benzoate period the number of erythrocytes per cubic millimeter of blood was a trifle below the count of the fore period. With E. C. M., taking the figures as they stand, the number of erythrocytes during both benzoate periods was lower than in the fore period or in the first after period. With J. F. L. the blood counts of the first four periods showed very little variation. If one were inclined to follow the indications of the bare figures, it might be said that sodium benzoate tends to increase the number of red corpuscles in the blood. Such a statement, however, would doubtless be misleading. What the results really imply is that the sodium benzoate fed has had no appreciable effect whatever upon the number of erythrocytes in the blood, or certainly has not interfered with those conditions of nutrition which are essential to the maintenance of a normal condition of the blood.

Regarding the leucocytes, or white corpuscles, the case of W. W. H. stands out conspicuously. For this we have no explanation to offer. There was with this subject a decided increase in the number of leucocytes during the first benzoate period, the first after period, and in the second benzoate period. It is hardly logical to believe that this increase in leucocytes was due to the benzoate, since if such were the case the first after period would hardly have shown an increase over the count of the first benzoate period, and, secondly, during the second benzoate period, when the larger doses were taken, an increase rather than a decrease of leucocytes would have been expected. W. W. H. was not a robust subject, although practically well throughout the experiment with the exception noted under "Clinical observations." Aside from this peculiarity the leucocyte count with the different subjects can not, in our judgment, be interpreted as indicating any specific result in one direction or the other. White blood corpuscles are always prone to some fluctuation, and with the exception of subject W. W. H. there is throughout a fair degree of agreement. There is certainly nothing in the data presented under this head which would justify any other conclusion than that the leucocytes of the blood were not materially influenced by the sodium benzoate taken.

Regarding the hemoglobin content of the blood, the figures show without exception a slight increase as the experiment progressed. Here, again, we are inclined to the view that it would not be wise to say that sodium benzoate tends to increase the hemoglobin content of the blood. More consistent and more in harmony with the general results of our experiment is the statement that sodium benzoate, judging by these data, certainly does not tend to decrease the content of hemoglobin and does not interfere with that condition of good health which leads to the maintenance of a normal amount of hemoglobin in the blood.

## EFFECT ON THE FECES.

The feces of each subject were collected, when passed, on every day of the experiment, duly weighed and prepared for analysis. As is well known, chemical and bacteriological study of the solid excrement furnishes much valuable information regarding the influence of any substance ingested with the food on digestion, utilization of food, fermentation, putrefaction, and other changes more or less normal to the alimentary tract. Further, study of the feces may reveal the existence of incipient diarrhea, constipation, etc., important in their bearing upon the question of health. In the tables showing the daily records of urine, feces, etc., will be found the weights of feces passed by the individual subjects each day. Here, however, for convenience, we have brought together the average daily weight of the feces for periods of seven and ten days for each subject, so that comparison can be made of the fore and other periods, when benzoate was not given, with the periods when sodium benzoate was taken. Comparison of these figures makes it apparent that the daily weight of feces during the fore period was greater per day with each individual than in the later periods. other words, at first glance it might seem that sodium benzoate had tended to reduce the amount of excrementitious matter. This, however, is not strictly true. It will be remembered that in the first three periods, covering twenty-one days, up to July 26, the intake of protein food was larger than in the later periods. Likewise, in the earlier days of the experiment a larger proportion of green, cellulose-containing food was consumed. This would naturally tend to give rise to a larger weight of feces. If, therefore, we take the results after July 26 to the end of the experiment, it will be seen that the weight of moist feces per day was not materially affected. In other words, the volume of feces for the individual subjects was not uniformly different in the long first benzoate period as contrasted with the first after period, the second benzoate period, and the final period. Minor differences, to be sure, do appear, but the table

giving average weights, showing moist feces per day, clearly bears out the statement that there was no radical change in the volume of feces passed after the 26th of July, and consequently there can not be ascribed to sodium benzoate in the dosage taken any specific effect upon the volume of feces passed per day, it being understood that the total volume and general character of the food consumed each day were essentially the same.

Average weight of moist feves per day.

Regarding the content of water in the feces, the following table shows the average daily results for the periods indicated under the head "Date." Here, again, there is no marked effect to be ascribed to the benzoate. In the long first benzoate period each individual shows a slight increase in the percentage of water in the feces. It amounts, however, to only 3 to 4 per cent. To ascribe this slight difference to the specific action of benzoate would seem hazardous when the data during the second benzoate period, the dosage being largely increased, show no noticeable change in the water content of the feces. Obviously, sodium benzoate in the doses given to our subjects does not lead to diarrhea or any kindred trouble. So far as the bulk and water content of the feces is concerned, there is no indication of any deviation from the normal.

a Calculated from the weight of the air-dry material.

#### INFLUENCE ON DIGESTION AND UTILIZATION OF PROTEIN FOOD.

The amount of nitrogen contained in the feces is the best measure that we possess of the degree of digestion and absorption of the protein or nitrogenous foodstuffs. Knowing the amount of nitrogen in the daily food and collecting the feces of the corresponding 24 hours. a determination of the nitrogen contained therein will, by comparison with the nitrogen intake, show the extent of utilization of the ingested protein food. In this way is obtained an indication of the extent to which the nitrogenous food is digested and absorbed, and any fluctuation in the content of fecal nitrogen is to be associated with corresponding fluctuations in the extent of digestion and utilization. From the tables showing the daily record of the individual subjects, the intake of nitrogen in the form of food and output of nitrogen in the feces have been collected and brought together in the following tables, giving in summary form the average daily intake of nitrogen and average daily output of nitrogen in the feces for the different periods of the experiment, thus giving the degree of digestion and absorption of the daily food expressed in terms of nitrogen, per cent utilized. It may be added here that the nitrogen of the daily food (for details regarding nitrogen content of the food, see daily food charts) was determined by the Kjeldahl method with addition of mercuric oxide. Nitrogen of the feces was determined in a similar manner, using the dried material.

The following tables show the utilization of nitrogen by each subject during the fore period, from July 6 to July 19; during the first benzoate period, from July 20 to September 20; during the first after period, from September 21 to September 30; during the second benzoate period, from October 1 to October 28; and in the final after period from October 29 to November 7. In every case it will be found by scrutiny of the results that the utilization of nitrogen, meaning thereby the digestion and absorption of the protein food. showed at the end of the experiment a slight improvement over that at the commencement. Thus, with the subject W. W. H., during the fore period 89 per cent of the nitrogen was utilized; during the first benzoate period the result was likewise 89 per cent; during the first after period 91 per cent; during the second benzoate period 90 per cent; while in the final after period 90 per cent was utilized. This is a sample of the utilization of nitrogen by all the subjects in the different periods of the experiment. We are not disposed to imply that sodium benzoate tends to improve the utilization of nitrogen. The point to be emphasized is that there was no deterioration; no falling off in the completeness of digestion and absorption of the protein food. Such slight gain as is indicated by the figures, if of any significance at all, is to be attributed solely to the general improvement in the health of the individuals. In other words, the sodium benzoate taken during the experiment exercised no deleterious influence upon the digestion and utilization of the protein food.

#### INFLUENCE ON DIGESTION AND UTILIZATION OF FAT.

11.29

9.98

The extent to which the fat of the food is made available for the needs of the body is determined by ascertaining the amount of fat which passes through the alimentary tract in the feces. Knowing the amount of fat contained in the daily food, it is then easy, by a simple process of subtraction, to estimate the amount of fat per day, or in any given period of time, unabsorbed, and thus figure the extent of its utilization. Reference to the tables showing the daily food composition of the individual subjects will give the data for the intake of fat. Throughout the experiment, during the stated periods, all articles of food were carefully analyzed for their content of fat. During corresponding periods of time the fat of the feces was likewise carefully determined. In the tables showing the daily record of the

subjects will be found the amount of fat utilized during the different seven-day periods of the experiment. These data are brought together in the following tables, in which is shown the percentage utilization of the ingested fat for the fore period, the two benzoate periods, etc. From examination of these tables it is seen that in every case, with the exception of J. F. L., the utilization of fat showed a noticeable improvement throughout the experiment. Thus in the case of H. H. G. the average utilization of fat during the fore period was 95 per cent; during the first benzoate period, 96.6 per cent; during the first after period. 98 per cent; during the second benzoate period, 98 per cent; during the final after period, 98 per cent. These figures are practically duplicated with all of the subjects excepting J. F. L. In the case of the latter subject, while the difference is not great, there is a slightly diminished utilization of fat during the first benzoate period, viz, 96.6 per cent, as contrasted with 98 per cent in the fore period. In the second benzoate period, however, the utilization of fat amounted to 97.5 per cent, while in the last after period it was 98 per cent—the same figure as in the fore period. It is thus plainly apparent that, so far as analysis will show, the sodium benzoate fed was without any appreciable influence upon the digestion and absorption of the fat of the food. The slight improvement in utilization indicated by the majority of the figures is too small to have any special significance. The data are simply in harmony with the general fact that the subjects were throughout the experiment showing a slight improvement in their physical condition. In any event it is plain that sodium benzoate does not exert any deleterious influence upon the digestion and absorption of fat; certainly not in the doses employed in our experiment.

## INFLUENCE ON DIGESTION AS MEASURED BY THE SCHMIDT METHOD.

While chemical examination of the feces is competent to show any material change in the digestion of the protein or fat of the food, a substance such as sodium benzoate might exert a slight inhibitory effect upon the digestion of different articles of food without producing any marked change in the chemical composition of the feces. Further, it is well to employ additional methods to substantiate, if possible, the findings by chemical analysis. With this end in view, the feces of the individual subjects were at given periods examined carefully, microscopically and macroscopically, after the method employed by Schmidt, as described by Steele in Medical News, December 16, 1905. Most stress was laid on ascertaining whether

abnormal amounts of undigested muscle fiber, connective tissue, mucin, or starch grains would appear in the feces during the feeding of sodium benzoate. The reaction of the feces was likewise noted with litmus and mercuric chloride. Attention was also given to the possible occurrence of abnormal quantities of fat.

In making the test a special diet as recommended by Schmidt was given for two days, in which care was taken to avoid the ingestion of food rich in cellulose, seeds, skins of fruits, or other ingredients which are absolutely indigestible in the human alimentary tract. The feces for given periods were separated by means of lampblack. In examining the feces a portion about the size of an English walnut was ground up thoroughly in a mortar, with a small amount of water. The well-triturated material was then placed in a Petri dish and examined, both with and without the microscope, for unchanged muscle fibers, connective tissue, and mucin. For the detection of starch granules the slides were treated with a drop of iodine solution. In cases of doubt as to the presence of mucin or connective tissue a drop of dilute acetic acid was applied to the material. The reaction of the feces to litmus was determined by means of moistened litmus paper. The hydrobilirubin test was made by mixing some of the triturated feces with an equal volume of a saturated solution of mercuric chloride.

Examinations of the feces by this method were made on the following days: July 15 to 16, during the fore period; August 12 to 14, during the first benzoate period; September 2 to 4, likewise in the first benzoate period; September 23 to 25, in the first after period; October 23 to 25, in the second benzoate period; October 31 to November 1, at the beginning of the second after period; and November 3 to 4, in the final after period.

The results of these tests may be briefly stated as follows: The character of the feces appeared at all times to be normal. While there were occasionally small bits of connective tissue or muscle fiber, they could not be regarded as being present in abnormal amounts. Potato starch granules were rarely observed. The reaction to litmus was neutral or slightly acid. In the corrosive sublimate tests for hydrobilirubin a decided pink coloration was obtained in every instance. Except for the occasional presence of small bits of vegetable or fruit skins and seeds, the character of the feces seemed to be unchanged during the entire period of the investigation.

## INFLUENCE ON THE INTESTINAL FLORA.

With a view to ascertaining whether sodium benzoate exerts any influence upon the character of the bacteria of the intestines, comparative studies of the intestinal flora were made during the different periods of the experiment. For this purpose definite amounts of

feces (1 gram) were introduced into 10 cubic centimeters of physiological salt solution and triturated with a glass rod. Two or three platinum wire loopfuls of the suspension were spread over the surface of microscope slides and allowed to dry. The slides were then stained by the ordinary Gram method, and placed serially in trays. Thorough microscopic examinations were made to determine any marked differences in the nature of the flora during the various periods. For the first fourteen weeks the feces were stained twice a week, while during the remaining four weeks such stained series were prepared three times a week. The following statements are taken almost verbatim from Doctor Rettger's report of his findings:

To the practiced observer, so-called "normal feces" present a more or less definite appearance when stained by the Gram method. Slight, and in a few instances marked, differences may occur, but on the whole the slides tend to have a uniform character. The nature of the flora is frequently influenced by diet and by pathological conditions. In order to obtain a "normal" picture of the stained feces a large number of samples from all the subjects were examined during the first nonbenzoate period. These slides were then compared with those of the different benzoate, as well as nonbenzoate, periods.

The character of the "normal" slides may be described briefly as follows: Among the Gram-staining organisms the most prominent were the large or giant cocci (sewage streptococci) occurring single, in pairs or in chains of three or more. Along with these were a large number of smaller micro- or diplo-cocci, and still others that were quite small, like the pus cocci. Occasional giant bacilli would be seen, single, or in short chains and somewhat resembling B. ramosus. More numerous than these were smaller rods of the capsulatus-aerogenes type, and also the still smaller and more slender forms which were often decidedly curved (B. acidophilus?). Rarely the branching, club-shaped form (B. bifidus?) was seen. A small number of very small, thin rods like B. pyocyaneus were also usually present. These were frequently in pairs.

In the pink or red background, which largely predominated over the blue or violet, the most prominent organisms to be regularly seen were the very slender and long, often curved, rods (to a great extent like B. putrificus without its spore), and the short organism of the colon bacillus type. Mingled with these were a much smaller number of intermediate forms.

While there were numerous departures from the above picture, the differences were between individual slides, and not between different series or the slides of the different periods. For example, two samples of feces during the first benzoate period were marked by an unusually large number of Gram positive long, slender rods, while a third contained an excess of the Gram positive giant bacilli and

giant cocci, and the remaining three slides were apparently normal. In another series of the same period two of the slides contained an unusual number of the long, slender, often curved, Gram positive rods (B. acidophilus?), while the remaining four appeared to be normal. Again, in the same benzoate period, one of the slides showed a predominance of long, slender Gram positive bacilli and the Gram negative bacilli of the colon bacillus type. A second slide of this series was more Gram positive than was usually seen, while in two of the remaining four slides the giant and smaller cocci were greatly in excess over the normal.

In one of the slides of the second nonbenzoate period the Gram positive giant bacilli were numerous, while in a second the cocci largely predominated, and in a third of the same series there were very few of the long, slender Gram negative forms, but an abundance of the Gram negative organisms of the colon bacillus type. In another slide of the same series Gram positive bacilli of all types were present in large numbers.

The slides that were prepared during the last four weeks of the investigation were much more uniform in appearance than at any time before. These four weeks covered a large part of the last or high benzoate period and the entire last nonbenzoate period. Although special emphasis was placed on the comparative study of these slides, it was impossible to note any differences whatever between the feces of the two periods.

There is no evidence in the data obtained that the ingestion of sodium benzoate visibly affected the character of the intestinal flora, as revealed by the Gram's stain and microscopic examination. While there were marked differences between different slides, it was impossible to associate any of the variations with any of the benzoate periods. The differences were those of individual feces and not of any particular series or groups of series.

## FERMENTATION TESTS WITH THE FECES.

These tests were made with dextrose (1 per cent) bouillon, in Smith fermentation tubes. The tubes were inoculated with one platinum loopful of the suspension of feces (1 gram feces in 10 c. c. of saline solution), and kept at incubator temperature for 20 to 24 hours. Duplicate tubes were always employed, and the average volume of gas in the closed arm noted. A second examination was made at the end of about 48 hours. As the results of the second examination rarely differed from those of the first, only one set of figures are given here, namely, those obtained at the end of the first incubation period.

As will be seen from the accompanying tables, the average amount of gas during the benzoate periods was slightly less than when no

benzoate was given, perhaps implying a slight degree of inhibition on the development of gas-producing bacteria. The differences are so slight, however, that no special significance can be attached to them.

Percentages of gas in closed arm of tube.

# SEDIMENTS IN BOUILLON AND IN THE DEXTROSE-BOUILLON FERMENTATION TUBES, INOCULATED WITH FECES.

The sediments in cultures 24 hours old were stained by the Gram method, and examined for the purpose of observing any influence that the ingestion of the sodium benzoate might have on the character of the sediments.

It was found that the bouillon sediments were fairly uniform throughout the investigation. They consisted largely of the colon bacillus, often in practically pure form. Occasionally spore-bearing bacilli of the *subtilis* type were present in noticeable quantities;

also streptococci and rather large Gram positive bacilli somewhat resembling the *Bacillus aerogenes capsulatus*. The irregular branching Gram positive organism and the slender G+ curved rods were rarely observed. None of these forms could be associated with any particular benzoate or nonbenzoate periods.

In the sediments of the dextrose-bouillon fermentation tubes greater differences were noted. While the colon bacillus was usually the predominating organism, the slides frequently had a decidedly Gram positive appearance, due mostly to the presence of the large sewage streptococci and the smaller streptococcus form. and to the two Gram positive bacilli already described—the irregular branching organism (B. bifidus) and the long, slender, curved rod (B. acidophilus?). The larger rods of the aerogenes-capsulatus type were also frequently observed. The variations were, however, only between individual slides, and apparently had nothing to do with the ingestion of the benzoate. For example, the branching, often club-shaped, Gram positive organism, presumably Tissier's B. bifidus, was of rather common occurrence in the sediments from the feces of one of the men (H. H. G.) and seldom, if at all, in those of W. C. R. None of the above irregularities in the character of the sediments could be associated with any particular benzoate or nonbenzoate period.

## INFLUENCE ON THE PUTREFACTION PRODUCTS IN THE FECES.

For the detection of phenol, indol, and skatol 20 to 25 grams of feces were treated with 250 c. c. of water, acidified with 4 to 5 c. c. of dilute sulphuric acid and subjected to steam distillation until 150 c. c. of distillate were obtained. The distillate was then tested for phenol by boiling with a few drops of Millon's reagent. The reactions were noted as negative, slight, moderate, or strong.

Indol was at first detected in the distillate by the use of two reagents, concentrated nitric acid and Ehrlich's aldehyde (dimethylamidobenzaldehyde). The two tests were employed side by side for about six weeks, when the nitric acid test was discontinued. The method of testing with Ehrlich's aldehyde was simply to add four or five drops of the aldehyde solution (made by dissolving 15 grams of the aldehyde in 300 c. c. of a 10 per cent solution of sulphuric acid). With small amounts of indol a rose to deep red color is obtained in the cold, the reaction being a very delicate one. The results are designated as negative, slight, moderate, and strong. As the amount of indol was at no time large, the Herter method of testing for it and removing it from solution with B-napthaquinone-sodium-monosulphonate was not regularly employed.

In the detection of skatol two reagents were used at first, namely, concentrated sulphuric acid and Ehrlich's aldehyde. The former was discontinued after about two months. On heating a solution containing skatol with Ehrlich's aldehyde solution a blue color is obtained, in contrast to the indol test. When indol and skatol are both present, the indol must first be shaken out with a solution of the B-naphthaquinone-sodium-monosulphonate, as described by Herter. (See Journ. Biol. Chem., II, p. 267, 1906.) Skatol was, however, not observed at any time, and only the indol-red reaction was obtained when indol was present, or there was no apparent reaction at all.

Comparison of the data in the two preceding tables shows that there was a slight increase in the amount of phenol detected during the last or high benzoate period. Whether this slight increase in phenol was connected with the large amount of aromatic group introduced associated with the large dosage of sodium benzoate is, of course, wholly questionable. In any event, considering the length of time the investigation was continued and the normal variations that may naturally arise from time to time, the results taken as a whole for phenol must be regarded as being fairly uniform, and hence as indicating little or no influence on the part of sodium benzoate.

Regarding indol, the only inference from the data presented is that the sodium benzoate was without influence on the amount of indol present in the feces.

As skatol was not present in the feces during any of the periods, no comment on this substance is called for.

Finally, it should be remarked that during the entire investigation the diet of the individual subjects was somewhat low in nitrogen. certainly lower than the usual or average diet, which fact in all probability accounts for the extremely small amounts of the above so-called putrefaction products in the feces of our subjects.

## EFFECT ON THE URINE.

Chemical analysis of the twenty-four hours' urine a of the individual subjects was made each day throughout the experiment. The only exception to this statement is in connection with hippuric acid, where at certain periods each day's urine was extracted separately, the alcoholic extracts united, and the hippuric acid determined in the mixture. All determinations were made in duplicate, and the figures given in the table of daily records are the average of two closely concordant results.

#### METHODS OF ANALYSIS.

Total nitrogen was determined by the Kjeldahl-Gunning method. Urea-nitrogen by Folin's method. (American Journal of Physiology, 1905, vol. 13, p. 45.)

Ammonia-nitrogen by Folin's method. (American Journal of Physiology, 1905, vol. 13, p. 47.)

Purine-nitrogen by the Krüger-Schmid method. (Zeitschrift f. physiologische Chemie, 1905, vol. 45, p. 1.)

Uric acid-nitrogen by the method of Folin. (American Journal

of Physiology, 1905, vol. 13, p. 49.)

Hippuric acid-nitrogen by the method of Lewinski. (Archiv für experimentelle Pathologie und Pharmakologie, 1908, vol. lviii, p. 399.)

Creatinine-nitrogen by Folin's method. (American Journal of Physiology, 1905, vol. 13, p. 48.)

Total sulphur by the method of Schulz. (Archiv f. d. gesammte Physiologie, 1907, vol. 120, p. 114.)

a Care was taken to prevent fermentative changes in the day's urine by liberal use of toluol.

Inorganic sulphur and ethereal sulphur by the method of Folin. (Journal of Biological Chemistry, 1905-6, vol. 1, p. 131.)

Neutral sulphur by difference.

Phosphate phosphorus by the uranium nitrate method, with potassium ferrocyanide as indicator.

Chlorine by the Volhard method.

Indican and total acidity by Folin's method. (American Journal of Physiology, 1905, vol. 13, p. 53.)

## EFFECT ON VOLUME OF URINE AND SPECIFIC GRAVITY.

Daily fluctuations in the volume of urine and the specific gravity may be studied by examination of the table of daily records. As a better means of comparison, however, we present in the two following tables the average volume of urine per day and the average specific gravity of urine per day for each subject during the seventeen periods of the experiment. Grand averages are likewise shown for each individual covering the fore period, from July 6 to July 19; the first benzoate period, from July 20 to September 20; the first after period, from September 21 to September 30; the second benzoate period, from October 1 to October 28; and the final after period, from October 29 to November 7.

Regarding the volume of urine per day, it is to be noted that all the subjects, with the exception of W. C. R., showed some little increase in the volume excreted during the first benzoate period as compared with the fore period. In most instances the increase is not very large. In two cases, namely, H. H. G. and E. C. M., the increase is somewhat conspicuous. The subject W. C. R., however, showed during the first benzoate period a noticeably smaller volume of urine per day as compared with the fore period. Secondly, it is to be noted that in the first after period of ten days the volume of urine dropped to the level of the volume excreted during the fore period in only one instance, namely, H. H. G. In three of the other cases the volume per day in the first after period was greater than during the benzoate period, while two of the subjects, W. W. H. and E. C. M., showed a slight falling off. During the second benzoate period, where the dosage was much larger, the volume per day was increased noticeably in the case of W. C. R. and J. F. L. With E. C. M. the volume fell off. Likewise in the case of L. M. L., when compared with the first benzoate period. Finally, in the last after period it is to be noted that the volume of urine remained essentially unaltered. The differences referred to are not very great, but there is a suggestion of a slight diuretic effect. How far this apparent diuretic effect is to be connected with the specific action of sodium benzoate and how much to other possible causes is to be questioned.

Thus, some consideration must be given, especially in connection with the first benzoate period, to the possible effect of the heat of midsummer in producing increased loss of water from the body with the accompanying increased desire for water, some of which would naturally pass out through the kidneys. That the slightly increased output of urine per day observed is perhaps to be associated with other causes than the benzoate is suggested at least by the fact that the volume of urine did not diminish noticeably in the after periods when no benzoate was taken. Obviously, however, any accurate determination of slight diuretic action would involve careful comparison of all intake of water with the output through different channels.

Regarding the specific gravity of the urine, it is to be observed that during the first benzoate period the specific gravity of the urine, with the exception of the subject W. C. R., was somewhat lower than in the fore period. This is in harmony with the increase in volume. Subject W. C. R. showed an average specific gravity during the first benzoate period of 1.018, as contrasted with 1.015 of the fore period. The volume of urine with this subject averaged 1,239 c. c. during the first benzoate period, as contrasted with 1,508 c. c. in the fore period. The change in specific gravity of the urine in all the subjects during the first benzoate period is to be ascribed solely to the slight changes in volume. During the second benzoate period the specific gravity suffered little change. In fact, it is quite apparent that the solid matters of the urine were not altered in amount under the influence of sodium benzoate, since the specific gravity remained essentially the same, except so far as it underwent slight modification incidental to the small changes in volume.

### EFFECT ON TOTAL NITROGEN.

The output of total nitrogen in the urine is best compared by studying the grand averages for each individual during the fore period, the first benzoate period, and the four subsequent periods. The following table gives the average output of total nitrogen per day for the six subjects during the seventeen weekly and ten-day periods, with the grand averages already referred to. Examination of the data shows that with the subjects H. H. G., W. W. H., L. M. L. and E. C. M. the total nitrogen of the fore period was in excess of that excreted during any of the later periods. The somewhat high total nitrogen output of the four subjects during the fore period is to be attributed to the larger intake of nitrogen from July 6 to July 26. This fact has already been commented upon in another connection, but it needs special consideration here, since it is well known that the nitrogen output runs more or less parallel with the nitrogen intake. In these four subjects the somewhat larger intake during this fore period was especially noticeable, and it is on this account that the

average daily nitrogen output of the four subjects in question is relatively high. In attempting to ascertain whether sodium benzoate exerts any influence upon the output of total nitrogen through the urine, it will be well to note particularly the average daily output of nitrogen on the periods subsequent to July 26. If, for example, comparison is made of the grand averages for the first benzoate period, the first after period, the second benzoate period, and the final after period, it will be seen that there is practically little or no change in the average output of nitrogen in any of the subjects. Somewhat striking, indeed, is the close agreement between the averages for the first benzoate period and the second benzoate period as compared with that of the first after period. Thus, in the case of H. H. G. the grand average for the first benzoate period was 8.68 grams of nitrogen per day; for the second benzoate period 8.64 grams of nitrogen per day; while for the period in between it was 8.53 grams of nitrogen per day. Again, in the case of L. M. L. the average output of nitrogen per day during the first benzoate period was 9.47 grams; for the first after period 9.43 grams; for the second benzoate period 9.42 grams. Still again, in the case of E. C. M. the average output of nitrogen per day during the first benzoate period covering two months was 9.82 grams; during the first after period 9.83 grams; during the second benzoate period of a month 9.43 grams. It is perfectly obvious, therefore, that sodium benzoate in the doses taken by our subjects does not affect the output of total nitrogen through the urine where the nitrogen intake remains essentially the same.

#### EFFECT ON THE UREA-NITROGEN.

Urea, more than any other one nitrogenous component of the urine, fluctuates in harmony with the amount of protein food ingested. Consequently, it is to be expected that the urea-nitrogen will show the same relatively high figure during the fore period in those subjects whose intake of nitrogen was high during the first two or three weeks of the experiment. In harmony with this view, it is to be noted that the average daily output of urea-nitrogen in the four subjects, II. H. G., W. W. H., L. M. L., and E. C. M., is comparatively high for the fore period.

The accompanying table, giving the amount of urea-nitrogen per day during the various periods of the experiment, shows that aside from these four high figures there is practically no change whatever in the average daily output of urea-nitrogen for any of the subjects in the different periods of the experiment. In other words, it is quite apparent from the figures presented that the urea-nitrogen excreted through the kidneys is not influenced in any degree by the ingestion of sodium benzoate.

### EFFECT ON AMMONIA-NITROGEN.

The table herewith presented, showing the average daily amount of ammonia-nitrogen excreted by the individual subjects during the different periods of the experiment, indicates quite plainly that this form of nitrogen is not influenced by sodium benzoate in the doses used in our experiment. The averages—except, as with the previous forms of nitrogen, the relatively high ammonia yield in the fore period owing to the larger intake of protein food—are in such close agreement that it is plain no specific effect in this direction can be attributed to sodium benzoate.

## EFFECT ON PURINE-NITROGEN.

The daily fluctuation in the purine-nitrogen of the individual subjects is seen from the daily charts. In the appended table, however, are shown the figures for the average daily content of this form of nitrogen during the seventeen periods of the experiment, with the grand averages for the fore period, benzoate periods, and after periods. Examination of the data shows that for some reason (presumably the larger proportion of meat in the diet) the excretion of purine-nitrogen per day is greater during the fore period than in any of the later periods. From July 20, the beginning of the first benzoate period, to the end of the second benzoate period there is very little change per day in the excretion of this form of nitrogen. The average daily excretion during the first benzoate period and during the first after period is almost identical, and with one exception the same is true for the daily average excretion during the second benzoate period. It is thus apparent that sodium benzoate does not have any tangible effect upon the output of purine-nitrogen. The only fact that would in any sense stand opposed to this conclusion is the relatively small

average output of purine-nitrogen per day during the final after period. It might be said, for example, that in the final after period the purine-nitrogen excretion drops off because of cessation in the dosage of benzoate. If this were the case, a similar result would naturally be expected in the first after period. This, however, the data show is not the case. There is no indication, except possibly in the case of W. W. H., of any marked tendency on the part of sodium benzoate toward changing noticeably the excretion of purine-nitrogen. We must conclude that the excretion of this form of nitrogen through the urine is not materially modified by the ingestion of sodium benzoate in the doses made use of in our experiment.

#### EFFECT ON URIC ACID-NITROGEN.

The accompanying table, giving the average daily output of uric acid-nitrogen during the different periods of the experiment, shows quite plainly that the excretion of this form of nitrogen is not changed in any degree by the sodium benzoate taken. Somewhat noticeable, indeed, is the close agreement in the average daily output of uric acid-nitrogen during the first benzoate period and during the second benzoate period in the case of the subject H. H. G., as well as in E. C. M., W. C. R., and L. M. L. In fact, the data speak for themselves quite clearly, that sodium benzoate is without effect upon the excretion of uric acid.

### EFFECT ON CREATININE-NITROGEN.

The accompanying table, showing the average daily excretion of creatinine-nitrogen for the individual subjects during the seventeen periods of the experiment, makes it quite clear that here likewise there is no influence exerted by sodium benzoate which can be noted. The figures giving the grand averages for the fore period, first benzoate period, first after period, second benzoate period, etc., with the different subjects, are so closely alike that the conclusion above is thoroughly justified by the results.

#### EFFECT ON HIPPURIC ACID-NITROGEN.

In considering the effect on the excretion of hippuric acid-nitrogen it is to be remembered that hippuric acid is not wholly, at least, a product of ordinary protein katabolism. The appearance of hippuric acid in the urine is dependent in large measure upon the amount of benzovl-containing substances introduced into the system. The other factor contributing to the production of hippuric acid is the amount of glycocoll available in the system. Under ordinary conditions of body metabolism there is always a sufficient amount of glycocoll present to combine with any ordinary amount of a benzovlcontaining radical to make hippuric acid, this acid being benzovlglycocoll. In view of these facts, it is obvious that the taking of sodium benzoate will naturally be followed by an increase in the amount of hippuric acid-nitrogen contained in the day's urine. Hippuric acid-nitrogen was not determined each day of the experiment, as already noted, but sufficient data are available to construct a table showing in a general way the average daily output of hippuric acid-nitrogen for different periods of the experiment. The table appended shows that during the first benzoate period the average daily output of hippuric acid-nitrogen was in some cases lower than the average daily output in the fore period, while in other cases the increase was so slight as to be hardly noticeable. This is due to variations in the character of the food. It is a significant fact, having bearing upon the present experiment, that the excretion of hippuric acid in the urine can be easily increased or decreased by modifying the diet. If it is desired to increase the hippuric acid output it is simply necessary to eat fruits, such as cranberries, huckleberries, plums, and other articles rich in benzoyl radicals, in which case the output of hippuric acid in the urine is increased. the fore period on some days a diet intentionally designed to give a high hippuric acid yield was prescribed, and it is significant that the average output of hippuric acid during this fore period was in many cases as great as in the first benzoate period, when 0.3 gram of sodium

benzoate was given daily. In the first after period it is to be noted that there is a little drop in the output of hippuric acid-nitrogen as compared with that of the first benzoate period. In the second benzoate period, where the dosage was large, the average daily output of hippuric acid-nitrogen was correspondingly increased. Somewhat noticeable is the fact that in the final after period the excretion of hippuric acid-nitrogen still continued high, showing a tendency for the benzoate to lag. In some cases, indeed, notably in H. H. G. and W. W. H., the average output per day was greater in the final after period than during the benzoate period. In conclusion then it may be stated that sodium benzoate, in harmony with well-known physiological facts, did in all these subjects, when the dosage was sufficiently large, give rise to an increased output of hippuric acidnitrogen. This, however, is not to be interpreted as implying a disturbance of the nitrogen metabolism of the body by sodium benzoate, but is simply a measure of the combination of the benzovl radical taken with the preexistent glycocoll.

### EFFECT ON THE DISTRIBUTION OF NITROGEN.

So far, we have confined our attention in referring to the different forms of nitrogen excreted through the urine to the average daily output in grams. We may next advantageously consider how far sodium benzoate tends to disturb the average distribution of nitrogen, i. e., how far the percentages of the different forms of nitrogen figured on the total nitrogen are changed. In the tables showing the distribution of nitrogen and sulphur in the urine, will be found the daily percentages of the different forms of nitrogen for each individual. For comparison, however, tables are appended for each subject giving the daily average distribution of nitrogen for the different periods, together with the grand averages for the fore period; first benzoate period; first after period; second benzoate period; and the final after period. As is well known, about 85 per cent of the total nitrogen of the urine is ordinarily in the form of urea. This percentage, however, is dependent in a measure upon the amount of protein food taken.

Comparison of the six tables following shows that in the first benzoate period the percentage of urea-nitrogen, i. e., the percentage of urea-nitrogen figured on the total nitrogen, is not essentially different from that of the fore period. In the case of W. W. H. and L. M. L. there is a slight decline, whereas in E. C. M. and W. C. R. there is a slight rise. These differences, however, are not sufficiently marked to have any significance. What is conspicuous, however, is the somewhat noticeable drop in the percentage of urea in all the subjects, with the exception of J. F. L., during the second benzoate period. At first glance this might be attributed to some specific action on the part of sodium benzoate. A little thought, however, will show that this does not necessarily follow. During the second benzoate period the daily intake of the benzovl-containing radical was fairly large, and there resulted a correspondingly large increase in the output of hippuric acid. In other words, the ingested benzoic acid combined with the requisite amount of glycocoll and was excreted through the urine as hippuric acid. In the absence of the benzoic acid radical the glycocoll would have been decomposed into urea. The slight decrease in the output of urea during the second benzoate period, therefore, was not due to any diminution in the amount of this form of nitrogen, but simply to the withdrawal of a certain amount of glycocoll which was eliminated as hippuric acid, thus escaping conversion into urea.

Careful scrutiny of the figures for the percentages of ammonianitrogen, purine-nitrogen, uric acid-nitrogen, and creatinine-nitrogen shows no marked variation during the different periods of the experiment. Slight fluctuations do appear here and there, but they are not sufficiently marked or regular to have any special importance. There is, possibly in the case of L. M. L. and W. W. H., a tendency for the percentage of creatinine-nitrogen to increase somewhat during the later stages of the experiment. This increase, however, is not large and can not have, it is thought, any particular significance.

## EFFECT ON TOTAL SULPHUR.

The daily excretion of sulphur through the urine is recorded in the tables giving the daily record of the individual subjects. Here, however, we have arranged, in tabular form, the daily average output of total sulphur for the various subjects during the seventeen periods of the experiment, with the grand averages for the fore period, benzoate periods, etc. As is well known, there is ordinarily a certain definite relationship between the extent of protein metabolism and the output of sulphur, since considerable of the sulphur of the excretion comes from the breaking down of protein. In view of these facts, therefore, we should expect during the fore period, in harmony with the larger intake of protein food and the corresponding increase in protein metabolism, a larger output of total sulphur than in the subsequent periods. This is what the figures in the appended table show in practically all of the subjects. During the first benzoate period the average daily output of total sulphur for J. F. L., for example, was 0.702 gram. During the first after period the average daily output was 0.712 gram; during the second benzoate period 0.689 gram; and in the final after period 0.691 gram. As is seen, these figures, which are more or less generally duplicated in the other subjects, show very little difference. There is perhaps a slight tendency for the sulphur output to diminish somewhat during the benzoate periods. The differences, however, are so small as to have little significance. So far as total sulphur is concerned, therefore, we are not disposed to ascribe any noticeable effect on the part of sodium benzoate.

#### EFFECT ON INORGANIC SULPHUR.

With this form of sulphur the figures for the average daily output during the different periods of the experiment are in close conformity with the general conclusions regarding the total sulphur. During the fore period when the food intake was relatively large, the amount of inorganic sulphur exereted per day was correspondingly high. The daily averages, however, for the first benzoate period, the first after period, the second benzoate period, and the final after period show very little difference. We must conclude, therefore, that sodium benzoate is without influence on the output of inorganic sulphur through the urine.

#### EFFECT ON ETHEREAL SULPHUR.

The table of daily averages appended shows throughout a very close agreement. The grand averages for the fore period, first benzoate period and the subsequent periods are very nearly identical in all of the individuals. The conclusion therefore is that the production and output of this form of sulphur is not influenced in any tangible degree by the doses of sodium benzoate taken.

#### EFFECT ON NEUTRAL SULPHUR.

The daily averages, together with the grand averages, for the excretion of neutral sulphur through the urine, shown in the accompanying table are not quite in such close agreement as the preceding sulphur figures. It is to be remembered, however, that the data for neutral sulphur are obtained by difference. Consequently, slight variations are here liable to be magnified somewhat. The daily average figure for the first benzoate period in every individual is noticeably higher than the daily average during the first after period. Between the first after period and the second benzoate period, however, where the largest difference would be looked for if sodium benzoate had any specific effect, there is little or no difference in the average daily excretion, the grand averages for the two periods being essentially the same. This is likewise true, in some of the individuals at least, with regard to the final after period. Hence, we are not disposed to attribute any specific action to sodium benzoate in influencing the excretion of neutral sulphur through the urine.

#### EFFECT ON THE DISTRIBUTION OF SULPHUR.

Having presented the data bearing upon the output of the different forms of sulphur through the urine in grams per day, we may next consider how far sodium benzoate tends to disturb the average distribution of the sulphur, i. e., how far the percentages of the different forms of sulphur calculated on the total sulphur are changed. the tables showing the daily distribution of nitrogen and sulphur in the urine will be found the daily percentages of the different forms of sulphur for each individual. For convenience, we append here tables for each subject giving the daily average distribution of sulphur for the different periods, together with the grand averages for the so-called normal periods and the two benzoate periods. Comparison of the grand averages shows, first, that the daily percentage of inorganic sulphur during the first benzoate period is somewhat less in every individual than during the fore period. Further, during the first after period the percentage of inorganic sulphur in every instance rises somewhat, approximating to the daily average output during the fore period. During the second benzoate period, however, when the larger doses of benzoate were given, the average daily output of inorganic sulphur remains substantially stationary, in some individuals falling slightly, in others rising slightly. In the final after period, the inorganic sulphur tends to fall off as compared with the average daily excretion during the preceding benzoate period. The only exception to this rule is in the case of H. H. G. As there is a

lack of any conformity in these fluctuations, however, we are not disposed to consider them as having any special meaning.

Regarding the percentage distribution of ethereal sulphur, comparison of the grand averages for the different periods shows, in most cases, a fairly close agreement. Thus, with the subject L. M. L. the average daily output of ethereal sulphur for the fore period was 6.4; for the first benzoate period, 6.2; for the first after period, 6.9; for the second benzoate period, 7.5; for the final after period, 7.5. These differences are more or less typical of what is to be seen in connection with the other subjects of the experiment. In one or two cases the variations are somewhat more noticeable, but there is no such degree of uniformity as would imply any definite or specific action on the part of the benzoate.

Regarding the percentage distribution of neutral sulphur, the results point to the same general conclusion. During the first benzoate period there is a tendency for the neutral sulphur to be increased as compared with the average daily proportion during the fore period. During the second benzoate period, however, with the larger dosage, the percentage of neutral sulphur is either unaltered, as compared with the first after period, or is diminished somewhat. In one instance there is a slight increase. The figures taken together, however, fail to show any action that is at all specific or peculiar.

#### RATIO OF SULPHUR TO NITROGEN.

Changes in the metabolism of the body, either of nitrogen metabolism or sulphur metabolism, induced by sodium benzoate would naturally lead to changes in the ratio of sulphur to nitrogen in the urine. The three tables which follow show the ratio of sulphur to nitrogen for each individual during the different periods of the experiment, the grand averages being perhaps best adapted for simple comparison. Critical study of the tables shows no appreciable change in the ratio under the influence of sodium benzoate. Thus, with the subject H. H. G. the average daily ratio of sulphur to nitrogen for the fore period is 1:13.4; for the first benzoate period, 1:13.6; for the first after period, 1:14.5; for the second benzoate period, 1:14.7; for the final after period, 1:14.2. Again, with the subject W. W. H. the average daily ratio of sulphur to nitrogen during the fore period is 1:14.2; in the first benzoate period, 1:13.0; in the first after period, 1:14.2; in the second benzoate period, 1:14.0; in the final after period, 1:14.0. It is plain that differences such as these, which are more or less typical of all of the individuals, have no significance and indicate quite clearly that sodium benzoate in the doses taken by our subjects has no disturbing influence on the relative excretion of sulphur and nitrogen.

#### EFTECT ON PHOSPHATE-PHOSPHORUS.

Possible effect of sodium benzoate on the phosphorus metabolism of the body can best be detected by noting such changes as may occur in the excretion of phosphorus through the urine. In the tables showing the daily composition of the urine the phosphatephosphorus excreted each day by the different individuals is shown. In the table here appended is given the average daily output in grams for the seventeen periods of the experiment, together with the grand averages for the fore period, the first benzoate period, etc. Comparison of these figures shows a lack of any distinct effect on the part of the benzoate upon the phosphate-phosphorus excreted.

The average daily output for the fore period is in several cases higher than in the after periods, but between the first benzoate period, the second benzoate period and the two other periods there is no appreciable difference in the average amount of phosphorus excreted each day. The conclusion is therefore obvious that sodium benzoate does not exert in the doses taken by our subjects any influence upon the excretion of phosphate-phosphorus, and consequently cannot be accredited with any noticeable influence upon the phosphorus metabolism of the body.

#### RATIO OF PHOSPHORUS TO NITROGEN.

Possible disturbance of the ordinary relation between phosphorus metabolism and nitrogen metabolism has been sought for by calculating the ratio of phosphorus excreted to nitrogen excreted per day. The three following tables give the average daily excretion of the two elements for the periods indicated, with the ratio of P: N. Study of the figures presented shows on the whole a remarkable degree of uniformity for the different individuals throughout the entire experiment. Thus, with the subject E. C. M. the ratio of phosphorus to nitrogen for the fore period is 1:13.3; for the first benzoate period, 1:13.4; for the first after period, 1:13.4; for the second benzoate period, 1:13.8; for the final after period, 1:13.1. While these figures for E. C. M. are perhaps closer than in most of the other individuals, still throughout there is a very close agreement; so much so that it is obvious sodium benzoate does not disturb in any degree the ratio between the output of phosphorus and nitrogen. Here and there a slight discrepancy may be found, but the majority of the results surely point to a lack of any tangible influence on the part of sodium benzoate in changing the ratio of these two elements.

#### EFFECT ON INDICAN.

The indican of the urine is generally considered as connected, in some measure at least, with intestinal putrefaction by which indol is formed. This being the case, the indican of the urine becomes to some extent a measure of the putrefactive processes in the intestine. It is interesting to note, therefore, the possible effect of sodium benzoate upon the amount of indican in the urine. The tables giving the daily composition of the urine show the fluctuations from day to day with the different individuals. The accompanying table, dealing solely with averages, gives the average amount of indican per day for each individual for the seventeen periods of the experiment, while the grand averages show the amount excreted for the fore period, first benzoate period, second benzoate period, etc. figures for the fore period are, in several cases at least, relatively high, but in the first benzoate period and the later periods the average output for each individual shows very little change. We might draw the inference, comparing the data of the fore period with the data of the subsequent periods, that sodium benzoate tends to lower indican production. Probably, however, the somewhat lower figures for indican after July 20 are associated, in a measure at least, with

the lowered intake of protein food. If comparison is limited to the first benzoate period and later periods, there is very little suggestion of any marked effect on the part of the benzoate. Taking all the data into consideration, we think the conclusion is justified that sodium benzoate in the doses used in our experiment and under the conditions of relatively low protein intake does not exert much, if any, influence upon the amount of indican in the urine.

#### EFFECT ON SODIUM CHLORIDE.

While the sodium chloride of the urine ordinarily has little significance except as indicating the amount of salt taken with the daily food, yet for completeness chlorine was determined each day, and the following table giving the average amounts of chlorine as sodium chloride for the different periods of the experiment is presented. Comparison of the grand averages shows a fairly close agreement in the daily output of chlorine. There is no change to be noted in those periods when sodium benzoate was taken. The output of chloride runs practically unchanged, with here and there a slight fluctuation, which, however, can have no special significance.

#### EFFECT ON TOTAL ACIDITY.

The accompanying table giving the average total acidity of the urine, expressed in grams of oxalic acid, for the different periods of the experiment, shows very little variation for the different individuals. In the fore period the average daily acidity was higher than in the later periods. There is a tendency, noticeable in all of the subjects, for sodium benzoate to lower the acidity of the urine slightly. This conclusion is based upon the figures of the fore period, combined with the figures showing the average daily acidity during the final after period. Taking these two groups as standards of comparison, it is plain that during the first benzoate period and in the second benzoate period the acidity tends to fall. The differences are not great, but there is suggested an influence here which is worthy of notice.

#### EFFECT ON PHENOL AND AROMATIC OXY-ACIDS OF THE URINE.

For the detection of these substances the following method was pursued: Three hundred cubic centimeters of urine (day's urine diluted to 1800 c. c.) were acidified with 5 c. c. of dilute sulphuric acid (1:4) and subjected to steam distillation until 150 c. c. of distillate were obtained. In the heating with acid the combined phenol in the urine is broken up and the phenol allowed to pass over in the distillate. The distillate was tested for phenol with Millon's reagent and the results studied in a comparative way. There were no appreciable differences.

The distillation was then resumed and allowed to continue until 300 to 350 c. c. of liquid had been driven over. At this stage it was soon found that very little, if any, phenol remained in the distillation flask. The contents of the flask were then thoroughly shaken with 150 c. c. of ether for the removal of the aromatic oxyacids. After evaporation of the ether the residue was extracted with 50 c. c. of boiling water, and the aqueous solution treated with Millon's reagent. A light rose to deep red color was taken as an indication of the presence of aromatic oxy-acids. The reactions were again studied as to their comparative intensities, and are indicated as 0, mild, moderate and strong.

As will be seen from the table, the results of the first three or four examinations for oxy-acids were negative. After that a slight or moderate reaction was obtained until toward the end of the experiment, when the amounts of aromatic oxy-acids were considerably increased. The strong reactions were given soon after the close of the high benzoate period; and for six weeks these larger amounts were but slightly, if at all, reduced.

Whether the presence of the aromatic oxy-acids in the urines is due to the benzoate administered is extremely questionable. A number of normal urines which were tested in the same manner gave widely different results. In some no reaction whatever could be obtained, while others gave a mild or even moderately strong reaction.

The persistence of the aromatic oxy-acids long after the close of the last benzoate period may possibly be due to causes other than the benzoate; or, if the benzoate does play some part, it may be explained on the hypothesis that after ingestion of the larger and repeated doses of sodium benzoate the latter is not eliminated at once, but is stored up in the body and gradually eliminated, partly as oxy-benzoic acid (an aromatic oxy-acid). This view, however, appears to us improbable. Further observations are being made in order to arrive at a more definite conclusion regarding these aromatic

oxy-acids. Finally, it should be emphasized that these acids occur in exceedingly small quantities, so that their presence, while interesting, presumably has no bearing upon the problem under consideration.

# EFFECT ON THE HIPPURIC ACID OF THE URINE.

As stated in another connection, benzoic acid, benzoates, and benzovl-containing radicals taken into the alimentary tract appear in the urine as hippuric acid. If the amount of benzoic acid introduced is large -- more than sufficient to combine with the glycocoll present in the system to form hippuric acid -then other combinations are possible, such as benzovl-glycuronic acid, which appears in the urine. It is rare to find benzoic acid itself uncombined or a salt of benzoic acid in the urine. In no one of our subjects was any trace of benzoic acid or benzoate found in the urine. Benzovl-glycuronic acid is characterized by a strong reducing power. Examination of the daily urines of all the subjects, especially during the high benzoate period, failed to show any reducing power. Consequently, benzovl-glycuronic acid could not have been present; certainly not to any extent. other words, even with the larger doses of sodium benzoate, the benzoic acid given the subjects was eliminated, in large measure at least, through the urine as hippuric acid.

The normal urine of man practically always contains a certain amount of hippuric acid. This is due, in large measure at least, to the presence of benzoic acid or benzoyl-containing radicals in the food. Certain articles of food, such as various berries, plums and prunes, are relatively rich in benzoyl-containing radicals. It is therefore easy to arrange a diet in which considerable benzoic acid or benzoyl-containing groups may be introduced with the food.

On July 7 and 8, and again on July 22 and 23, all of the subjects were given a diet in which, so far as it was possible, benzoyl-containing substances were reduced to a minimum. Then, on July 9 and 10, the daily diet of each subject was especially constructed so as to contain considerable benzoic acid or benzoyl radicals by addition of raspberries, currants, and huckleberries. A table is appended showing the amount of benzoic acid (present as hippuric acid) in the urine of the individual subjects on certain dates designated. Likewise is shown the amount of benzoic acid added to the food when sodium benzoate was administered.

Attention is called, first, to the amount of benzoic acid obtained as hippuric acid through the urine on July 7 and 8, when the diet was freed as far as possible from benzoyl-containing articles. It will be noticed that on these two days the amount of benzoic acid per day, contained in the urine of the individual subjects as hippuric acid. varied from 0.058 gram to 0.303 gram. This means that under ordinary conditions of diet where fruits are eliminated there is a sufficient

amount of benzoyl-containing radicals in the food to give rise to an amount of hippuric acid equal to a maximum of 0.3 gram of benzoic acid per day. On July 9 and 10, however, when huckleberries, raspberries, and currants were added to the daily diet, the amount of benzoic acid obtained from the urine as hippuric acid rose to a maximum of 1.154 grams, with a minimum of 0.356 gram. In the majority of the subjects, however, the amount of benzoic acid in the urine each day as hippuric acid was between 0.8 and 0.9 gram.

On July 22 and 23, as stated, the daily diet was as free from benzovl-containing compounds as it was possible to arrange it, but on these days 0.252 gram of benzoic acid was given as sodium ben-Study of the figures in the tables for benzoic acid obtained from the urine as hippuric acid shows that with the above dosage the output of benzoic acid in the urine per day for all six subjects was very much below the amount of benzoic acid obtained from the urine on July 9 and 10, when no sodium benzoate was administered, but with huckleberries, raspberries, and currants added to the diet. In fact, all through the first benzoate period when the amount of benzoic acid taken daily equaled 0.252 gram, the benzoic acid in the urine as hippuric acid never equaled the maximum figure obtained from the subjects when no benzoate was given, on a diet reinforced by huckleberries, currants, and raspberries. Reference to the food charts for July 9 and 10 shows that the quantity of these berries taken was not large, 155 grams of fresh huckleberries being perhaps the maximum The inference, therefore, is that the amount of benzovlcontaining radicals naturally present in the food on July 9 and 10 was much larger than the amount of benzoic acid introduced with a daily dosage of 0.3 gram of sodium benzoate.

Study of the data in the appended table obtained during the second benzoate period when the dosage was still larger shows an output of benzoic acid as hippuric acid, more or less comparable to the amount of benzoic acid ingested. Thus, in the week of October 15 to 21 the daily intake of benzoic acid was 1.680 grams. The average daily output of benzoic acid as hippuric acid varied with the different subjects from 1.212 grams to 1.657 grams. Or taking the entire higher benzoate period of one month, when the average daily intake of benzoic acid was 1.596 grams, the average daily output of benzoic acid as hippuric acid for the different individuals ranged from 1.102 grams to 1.559 grams.

Finally, attention should be called to the fact that from October 29 to November 7, when sodium benzoate was no longer taken, the average daily output of benzoic acid in the form of hippuric acid varied in the different subjects from 1.251 grams to 1.700 grams, thus showing that the aromatic group introduced in the way indicated is somewhat slow in leaving the system.

#### EFFECT ON THE NITROGEN BALANCE.

As will be seen from examination of the tables showing the daily intake of nitrogen and the daily composition of the urine and feces, a nitrogen balance was struck at given periods, of seven or ten days, with all of the subjects. In the following tables the record of nitrogen balances for each individual is shown, giving the daily average intake of nitrogen in the food with the output of nitrogen through the urine and feces for the seventeen periods of the experiment, expressed in grams per day, together with the average nitrogen balance, likewise expressed in grams per day.

Examination of the results shows that on two occasions a minus nitrogen balance was obtained. The first case, that of W. W. H., occurred during the period of August 3 to August 9. This minus balance, averaging one gram per day, was due in large measure, without question, to the small intake of food incidental to an attack of corvza, which is mentioned under the head of "Clinical observa-

tions." The only other minus balance during the length of the experiment was in the case of W. C. R. in the latter part of the fore period, July 13 to 19, when the average daily nitrogen balance was -0.01 gram. In this case, as the figures indicate, the subject was practically in nitrogen equilibrium. Aside from these two cases all the subjects showed a plus nitrogen balance throughout the experiment. Critical survey of the data presented in the tables makes it quite clear that during the periods when the sodium benzoate was taken, whether the doses were small or large, there was no marked change in the nitrogen balance.

The daily average balance shows, it is true, some fluctuations, as might well be expected, but it is perfectly evident from the results that sodium benzoate does not have any specific effect upon the nitrogen metabolism of the body. If in some instances the plus balance seems smaller in those periods when benzoate was taken, it will be found on looking at the nitrogen intake for that period that in most cases the amount of nitrogen ingested was below that of the periods where the plus nitrogen balance was larger. In other words, the size of this plus nitrogen balance is governed mainly by the volume of nitrogenous or protein food ingested, and there is no influence apparent on the part of sodium benzoate in modifying the amount of this balance.

Taking into consideration all the data presented in connection with the urine, having in mind the quantitative changes of the different nitrogenous constituents, as well as the data covering the nitrogen intake and nitrogen output, it seems perfectly manifest that sodium benzoate in the doses taken by our subjects does not exert any appreciable influence upon those processes of nutrition which are ordinarily included under the term protein or nitrogen metabolism.

#### GENERAL CONCLUSIONS.

Due consideration of all the data presented in the preceding pages, together with careful study of the individual data of the various tables of results, leads to the following general conclusions: Sodium benzoate, in small and large doses, up to a maximum of 4 grams per day, is without disturbing influence upon the general health of the individual, so far as can be seen from clinical observations. There was no attendant loss of body weight; neither was there any disturbance of digestion, assimilation, or utilization of either the fat or protein food. Indeed, the subjects of our experiment showed a gain of weight and even an improved condition of digestion during the period of the experiment in which the action of sodium benzoate was tested.

Again, there was no deleterious influence on the part of sodium benzoate upon the blood, either on the number of crythrocytes, leucocytes, or the hemoglobin content of the blood.

Upon the less tangible processes of metabolism as indicated by the quantitative study of the urine, etc., there is no indication of any marked action. No changes of any special significance were to be

noted during the period when sodium benzoate was fed even in large doses, aside from a slight effect on the reaction of the urine, so that the conclusion is obvious that sodium benzoate does not exert, in small or large doses, any pronounced influence upon the processes of metabolism or of nutrition.

Sodium benzoate is without effect upon the production of nitrogen balance. Throughout our experiment a plus nitrogen balance was easily maintained, and in such fashion as to clearly indicate that sodium benzoate does not exert any harmful or disturbing influence.

In our judgment, therefore, based on the character of the results obtained in this study of the action of sodium benzoate on the general health and nutrition of man, there is no suggestion of any pronounced effect whatever produced by the salt in such doses as we have employed. We are of the opinion that sodium benzoate, in small and large doses, up to a maximum of 4 grams per day, is no more harmful or provocative of disturbance of the human organism than corresponding amounts of sodium chloride or common salt.

This conclusion, while based entirely upon the results of our investigation, is in close harmony with what is known regarding the occurence of benzovl-containing radicals in many natural products, which have long served as useful foods for mankind. As our results show, in harmony with well-known facts, the ordinary diet of man contains a sufficient amount of benzoic acid or kindred substances to give rise to appreciable quantities of hippuric acid in the urine. Further, huckleberries, cranberries, and other related fruits well recognized as noninjurious to health have in them amounts of benzovl radicals sufficient to form quantities of hippuric acid in the urine larger than the small doses of sodium benzoate fed in our experiment; thus making it apparent that some natural foods at least contain quantities of benzoate, or related substances, in amount equal to what was fed in our daily dosage with sodium benzoate, and that the system is well inured to the presence of moderate quantities at least of this aromatic group.

Finally, it may be added that the results of our experimental study make it evident that the admixture of sodium benzoate with food does not lead to any reduction in the quality or strength of such food; neither is the food injuriously affected thereby when the salt is added in small quantities or in large quantities, up to a maximum of 4 grams per day. Were the contrary true, we should expect to find in our experimental results indications of either a disturbance of digestion, an inhibition of the normal power to digest and assimilate the food treated with sodium benzoate, together with a tendency toward the production of a minus nitrogen balance, with possible loss of body weight.

### INVESTIGATIONS ON THE EFFECTS OF SODIUM BENZOATE ON THE HEALTH AND GENERAL METABOLISM OF MAN.

By JOHN H. LONG.

### INVESTIGATIONS ON THE EFFECTS OF SODIUM BEN-ZOATE ON THE HEALTH AND GENERAL METABOLISM OF MAN.

By John H. Long.

### INTRODUCTION.

I have attempted the solution of the problem presented to me through a series of laboratory and clinical observations carried out on six men consuming a controlled diet. The laboratory observations were mainly chemical and bacteriological, and were intended to disclose any change in the general metabolism, or character of the excretion of the men under study. The clinical observations were of the usual routine nature, but were noted with more than the ordinary care. I consider these observations as having, for the present inquiry, and under the conditions which obtain, no less value than the other set, and hence I am presenting them in all detail, as made from day to day. The somewhat monotonous bacteriological examination of the feces is given in the same detail, since the object of the report is to present all the observed facts which may have any bearing on the questions of the diet, general health and character of the metabolism and excretions of the subjects of the experiments.

The squad under observation in my laboratories consisted of six men who were all students of medicine, but who, during the progress of the tests, had other employment. At the beginning of the experiments the men were in normal health, but not in unusually good physical condition, since the work was begun at the end of the school year,

following rather heavy courses of study.

For general convenience the men were furnished with rooms in the same house, and the meals were prepared and served in a large vacated room in the college building adjoining the laboratory in which most of the analyses were made. The kitchen was screened off from one end of this room, and the meals were prepared by a professional cook who had had previous experience with metabolism work. This simplified many of our natural difficulties very greatly, and made it possible to maintain an accurate control over the daily dietaries in such a way as to permit a fairly close calculation of the caloric value of the food as weighed out and served.

Dr. S. R. Benedict, now professor of physiological chemistry in Syracuse University, had general charge of the dietaries and the chemical work connected with the investigation. The bacteriological work necessary and the medical oversight of the men were in the hands of Dr. W. H. Buhlig, professor of clinical pathology in Northwestern University. These gentlemen were in constant attendance at the laboratories, and the success of the investigations must be credited largely to their careful control of all conditions involved. Since the conclusion of the actual tests Mr. Frank Gephart, who took part in the analytical work, has rendered valuable aid in the numerous necessary calculations and the tabulation of results.

At the beginning of the observations the men on the squad were subjected to careful examination, and the facts given below with regard to previous medical history and condition were secured.

DURATION OF TESTS.—The first meals were served to the squad on June 29, and the last on October 30. The interval was divided into sixteen periods, the average length of which was about seven days, as the tables below will show. The actual administration of benzoate began on July 24, following three preparatory fore periods in which the diet habits of the men were closely studied.

DIET.—In this time and throughout the whole test the men were allowed a very ample diet, following their own tastes and desires as far as possible. The food was well prepared, and as served would be considered a good example of home cooking; the only modifications made were such as were rendered necessary to facilitate accurate sampling and analysis. Meats, for example, were always served in the minced condition, since uniform samples for analysis could not be secured in any other way. Gravy was served separately and was mixed in by the men at the table. Care was taken to serve the minced meat hot and in such manner as to relieve the monotony of the diet as far as possible. Jellies, custards, puddings, cakes, and other articles were always made in such a manner as to facilitate the subsequent work of the analysts. The location of the kitchen with respect to the laboratories and the office of the director added greatly in simplifying proper control here.

Dosage.—From July 24 to September 21, sixty days, each man received a dose of 300 milligrams daily of Merck's sodium benzoate, calculated as anhydrous, divided into three portions of 100 milligrams each. That is, the benzoate was given at each meal, and was measured out from an accurately prepared solution into some article of food which the men ate with a relish. At no time during the test did the men have any idea of the part of the food which contained the benzoate, nor did they know when the administration began or ended. No especial curiosity on the subject was manifest and the men did not act as if the food was in any way a deviation from the normal.

On September 22, after the completion of eight preservative periods, the dose of benzoate was increased to 600 milligrams daily, divided through the three meals. This dosage was continued through two periods of seven days each. Between the higher and lower preservative periods the feces of the men were marked off by the usual method of lampblack administration in capsules, which was the case following the next period, also.

On October 6, the fourteenth period, or the eleventh preservative period, began. On this date the dose was increased to 1 gram of benzoate daily, which was continued through eighteen days, that is, from October 6 to 23, inclusive. It was found easily possible to distribute this amount of benzoate through the three meals without

in any way attracting the attention of the men consuming the food. The eighteen days were divided into two periods.

The total amounts of benzoate administered were, then, as follows:

Periods.	Dura- tion.	Daily dose.	Total.
Fourth to eleventh, inclusive. Twelfth to thirteenth, inclusive. Fourteenth to fifteenth, inclusive.	Days. 60 14 18	Gram. 0.300 .600 1.000	Grams. 18.0 8.4 18.0
Total			44. 4

The men were kept under routine observation through an after period, No. 16, of seven days, and have been under general observation up to the time of the completion of this report, January 10, 1909. Following the official conclusion of the tests on October 31 two of the men on the squad, A. M. N. and C. H. S., continued the same general diet with a greatly increased dose of the benzoate. This was carried to 10 grams daily. In this they were joined by Mr. Frank Gephart, who had assisted in the weighing of the foods throughout the whole time, had worked in the laboratory, consumed the regular diet with the squad, and had lived under the same general conditions. On November 1 he began with relatively large doses. The effects of these large doses on the men will be referred to below.

Methods of analysis.—It is not necessary to go into details here; most of the results for the urine were obtained by aid of the well-known processes of Folin. For total sulphur, however, a method was worked out by Doctor Benedict which, when applied, gave very satisfactory results. This consisted, essentially, in oxidation of the urine through boiling down with copper nitrate and potassium chlorate, and subsequent fusion, as preliminary to precipitation.

In the determination of urea nitrogen a marked improvement and economy of time was effected by heating the urine in an autoclave with dilute hydrochloric acid. The process has been described by Benedict and Gephart in the November, 1908, number of the Journal of the American Chemical Society.

Collected in 24-hour periods, and of the urine daily analyses were made, excepting of the Saturday collection, which came into the laboratory Sunday morning. This was saved and mixed with the sample from Sunday; an analysis of the composite was then made. The urine was collected in bottles containing always a little toluene, and as a further precaution the bottles were kept in a large ice box in the intervals. When brought to the laboratory in the morning the reaction and specific gravity were taken, after which each urine

was diluted to a constant volume, 2,000 c. c., and aliquots taken for the several tests. This dilution to a standard volume greatly facilitates subsequent calculations.

The feces were collected and weighed for each twenty-four hours. Aligout portions were weighed out, after thorough mixing, and put in a separate container for analysis at the end of the period, which was generally seven days, as explained above. The bacterial tests, however, were made on the fresh samples.

For the separate collection of urine and feces a very convenient form of closet was employed which was suggested to me by Professors Grindley and Hawk, of the University of Illinois. One of these closets was kept at the laboratory and one at the rooming house.

EXERCISE—HOURS FOR MEALS.—The quarters rented for the men were in a comfortable house, about half a mile from the laboratory and diet kitchen. The six men occupied three rooms, the division being made according to the wishes of the men themselves. In addition to the walk between the two places the men had plenty of other exercise. Two of them carried papers early in the morning and had other work throughout the day. Three gave help in the analytical laboratory, and two, in addition to other work, had some janitor duties about the college. All were encouraged to play handball for a short time after dinner each day, and this exercise was generally taken.

Breakfast was served at 7:30, lunch at 12, and dinner at 6. men were put upon their honor as far as general conduct and consumption of other foods was concerned, and it is confidently believed that there were no violations of the advice of the director here. There was no restriction on the consumption of water. was unusually warm and any attempt to limit the amount of water drunk, or even to control it, would have worked a hardship. In every respect the men were supposed to lead lives as nearly normal as possible, and only such restrictions were made as were really necessary for the proper prosecution of the work.

With this brief introduction, which is doubtless sufficiently full for the purpose, we pass to the consideration of the data secured in the various examinations made. The general urine tests will be taken up first.

### DAILY FOOD CHARTS.

The following tables present the recorded numerical data concerning the daily bill of fare of the diet squad, and it will be recognized, as explained in the opening statement, that the diet is an ample one. The additions at the foot of each page show the total weight of food consumed daily, exclusive of tea and coffee, but including milk, the total nitrogen and fat consumption, and, in some cases, the estimated fuel value of the food. The total food weights have only relative value, because of the very variable nature of the items in the menu, but are suggestive and are therefore included.

The records in the fourth column under each subject are close approximations only. Enough additions are made for each period to show with a fair degree of closeness the extent of food consumption, measured in this way. The footings have naturally a much greater relative than absolute value.

It will be noticed that the men exhibit very different tastes: in one case, for example, the consumption of butter is abnormally high, while in another the milk consumption is very high. All the men were found to be very fond of sugar, which was used liberally directly and weighed as such, and also in the form of puddings, custards, and certain sauces, which were made sweeter than most people would desire. The fuel value of the various foods was calculated in part from the daily analyses and in part from the records of the cook, who worked under the observation of one of the laboratory assistants, and was able to state closely the amount of carbohydrate employed in various items. For some of the fruits and a few other things the values have been taken from the Atwater tables, published by the Department of Agriculture. In any event, the comparative values hold good, and this is the main object of the computations.

The nitrogen and fat additions have been used in computing the balances of the preceding tables, and the fuel values found have been summarized as shown below. A number of days from each principal period were taken at random, and the values for these days computed and added. From these additions the means were taken, and these are the figures given below for the fore period, the low preservative period, the first high preservative period, the second high preservative period, and the after period. It will be noticed that there is no characteristic change in the daily caloric values through the whole season; while for some of the men there is an increase in the calories used, for others there is the reverse change. In general the values remain high and show no relation to the administration of preservative.

### DISCUSSION OF RESULTS.

The figures in the above tables speak for themselves, but the most salient points for each subject may be best brought together by a presentation of certain of the results in the form of averages and ratios. Along with the data for the urine, the nitrogen and fat contents of the feces are given so as to facilitate the calculation of nitrogen and fat balances at the end of each period. The data concerning the nitrogen and fat intake are found in full in the complete food tables.

Two kinds of averages may be presented with advantage; in the one case the variations in the total nitrogen, urea, ammonia, purine, and other forms of nitrogen combination may be given, while in the other the data cover the percentage distribution of these forms. The short tables given below embrace condensations of this sort, as will be explained. Each subject will be followed through separately, and for each three tables will be presented. In the first we have the average daily output of certain forms of nitrogen in the five general periods into which the investigation may be divided—that is, in the fore period, the low preservative period (300 mg. daily), the first high preservative period (600 mg. daily), the second high preservative period (1 gm. daily), and finally the after period, with no preservative.

In the same table some data for sulphur and phosphorus will be given, and also figures for nitrogen and fat in the feces. The urine averages are secured by taking the means of the daily means, as given

in the footings of the columns of the above main tables.

In the two tables to follow we have the average daily composition of the feces, obtained by dividing the period results by the number of days in the period, and finally the very important percentage distribution of the nitrogen and sulphur in the urine. The value for each constituent is expressed in terms of the total nitrogen and total sulphur excreted in each period. The total sulphur for the fore periods is omitted because of some uncertainty as to the correctness of part of the determinations.

In the tables following the term *period* is employed in a wider sense than in the charts. Here we have condensed the 16 periods, of about one week each, into five main periods, distinguished by the amount

of benzoate added to the food.

### SUBJECT I (H. N. B.).

As the food tables will show, this man enjoyed a good appetite throughout the tests, with the exception of one or two occasions, and we find in the analytical results nothing to indicate any deviation from the normal metabolism. It is true that there are rather wide variations in the output of the several urinary constituents, but

## DISCUSSION OF RESULTS.

The figures in the above tables speak for themselves, but the most salient points for each subject may be best brought together by a presentation of certain of the results in the form of averages and ratios. Along with the data for the urine, the nitrogen and fat contents of the feces are given so as to facilitate the calculation of nitrogen and fat balances at the end of each period. The data concerning the nitrogen and fat intake are found in full in the complete food tables.

Two kinds of averages may be presented with advantage; in the one case the variations in the total nitrogen, urea, ammonia, purine, and other forms of nitrogen combination may be given, while in the other the data cover the percentage distribution of these forms. The short tables given below embrace condensations of this sort, as will be explained. Each subject will be followed through separately, and for each three tables will be presented. In the first we have the average daily output of certain forms of nitrogen in the five general periods into which the investigation may be divided—that is, in the fore period, the low preservative period (300 mg. daily), the first high preservative period (600 mg. daily), the second high preservative period (1 gm. daily), and finally the after period, with no preservative.

In the same table some data for sulphur and phosphorus will be given, and also figures for nitrogen and fat in the feces. The urine averages are secured by taking the means of the daily means, as given

in the footings of the columns of the above main tables.

In the two tables to follow we have the average daily composition of the feces, obtained by dividing the period results by the number of days in the period, and finally the very important percentage distribution of the nitrogen and sulphur in the urine. The value for each constituent is expressed in terms of the total nitrogen and total sulphur excreted in each period. The total sulphur for the fore periods is omitted because of some uncertainty as to the correctness of part of the determinations.

In the tables following the term *period* is employed in a wider sense than in the charts. Here we have condensed the 16 periods, of about one week each, into five main periods, distinguished by the amount

of benzoate added to the food.

### SUBJECT I (H. N. B.).

As the food tables will show, this man enjoyed a good appetite throughout the tests, with the exception of one or two occasions, and we find in the analytical results nothing to indicate any deviation from the normal metabolism. It is true that there are rather wide variations in the output of the several urinary constituents, but

these are irregular and fail to disclose any relation to the benzoate given with the food in the later periods. The uric acid and creatinine are particularly constant, while for the ammonia, the sulphur, and the phosphorus the changes are not marked and are not systematic.

It will be noted that the nitrogen and the fat in the feces show marked changes in the after period; for the first an increase and for the second a decrease. As this behavior is found in all the subjects, it will be commented on later.

# SUBJECT II (W. W. C.).

Much the same condition may be noted here as with Subject I. The total output of nitrogen is larger and there are marked changes in it of an irregular character. Attention is called to the increased elimination of nitrogen and decreased ether extract in the feces of the after period, but aside from this there is nothing in the figures of the three tables to point to any possible connection between dosage and metabolism. If there appears to be a slight increase of purine nitrogen, we find that this does not hold for the other subjects. The variations in the uric acid and creatinine nitrogen follow just the reverse order noted in Subject I, and therefore are not sufficient to point to any systematic relationship. An apparently marked change is shown in the distribution of the total sulphur, as it seems to increase toward the end of the investigation. But this condition is continued into the after period, and besides does not hold for the other subjects throughout. Considering all points it is clearly evident that the variations found in the urines of these periods are not outside the normal limits which should be expected in work covering four months in time.

### SUBJECT III (A. G.).

This man performed a regular part of the analytical work of the investigation and was throughout perfectly normal in his diet and habits. The diet was comparatively hearty, as shown by the food charts and the output of nitrogen. In considering the condensed data of the following tables there is nothing very striking in the nitrogen metabolism to be specially noted. The total nitrogen excretion is highest in the fore period and lowest in the after period, as was the case with Subject II, but as this relation does not hold for all the men it is evidently without significance. The uric acid, ammonia, creatinine, and purine excretions are very regular. both in amount and distribution, and here, as in the other cases, there is a very good correspondence between the nitrogen and the total sulphur of the urine. There appears to be a tendency toward the increase of neutral sulphur in the after period, but the ethereal sulphates remain nearly constant throughout. While the neutral sulphur is high with the absence of preservative, it is also high in some of the periods where the preservative was high. In the case of Subject VI it will be seen that the highest neutral sulphur falls in a low preservative period. It is clear, therefore, that we can not draw any definite conclusions from this fact. The peculiarities in the nitrogen and fat ratios in the feces are in evidence here. The condition of metabolism shown by the tables is strictly normal.

### SUBJECT IV (O. F. L.).

In this man the peculiarities of diet were extremely marked, and corresponding peculiarities of metabolism might naturally be looked for. Reference to the food tables will disclose the kind and amount of food preferred, of which milk was always a prominent item. A perfectly sufficient diet was consumed, however, throughout, with the exception of a short time in two periods, when the illness of a member of his family called him away over night. The urine and feces were saved, but for the time the food (carried with him) was

not abundant. This will account for the apparent negative balance. Aside from this the metabolism is remarkably normal and a good utilization of the food is evident. This is shown by the data for the nitrogen and the fat in the feces, as presented in the first of the following tables, and for the nitrogen elimination of all the periods, as shown in the second table following. It is not possible to discover any abnormal effect of the diet at any point of the whole four months of observation. If anything of this kind should obtain we should expect to find it in the distribution of the nitrogen of the urine, but here we discover a very uniform relation running from the beginning to the end, with no break at any point corresponding to the benzoate periods. The high neutral sulphur of one of the benzoate periods is matched by the same condition in the after period, and as a general conclusion we must look upon all the urines as normal and within natural limits.

### SUBJECT V (A. M. N.).

This man carried a part of the analytical work on the urine and was kept busy through the day. His exercise was secured in playing handball and in walking, in which his habits were very regular. The diet sheet is not in any way unusual. A consideration of the analyses shows the same general trend disclosed in the other men. with the urine nitrogen lowest in the after period, however. Corresponding to this we have a rather high percentage of nitrogen in the feces. The excretion of creatinine, ammonia, uric acid, and sulphur and phosphorus are regular. The indican figures are relatively high, but not the highest. There is at present no explanation for the marked variations in this factor between different individuals, but no special significance can be attached to it, as similar results are found in the routine analyses of urines in general. The neutral sulphur in this and the last case does not appear to be markedly increased in the after period, as was evident in the other men. the results here appear to be normal, with nothing to suggest a dependence on the ingested benzoate. The variations noted are not systematic enough to lead to any conclusion in this direction, except, perhaps, with reference to the fat and nitrogen of the feces in the after period, of which something will be said below.

### SUBJECT VI (C. H. S.).

This subject is blessed with a remarkably flexible appetite, and was always ready for any kind or variation in the diet. He had a newspaper route for the early and late hours, and during part of the time performed some janitor work in the college buildings. A study of the following sheets shows an interesting regularity in the course of the urinary and fecal exerction, with no variations of any note to point to an effect of the benzoate The excretion of the neutral sulphur is here much more regular than with the other men, while for the ammonia, the uric acid, and the creatinine we have almost constant values throughout. The importance of such facts must not be overlooked, since any disturbances in the general metabolism would undoubtedly show in some of these constituents of the urine or feces. The total nitrogen and the urea outputs are apparently more regular through the whole season for this man than for the others, and it will be noticed that like Subject I he shows a little increase here from the fore period to the first preservative period, while for some of the others there is a decrease. As far as can be determined by the analyses of the excreta, it is evident that this man has remained in normal condition through the tests, and his metabolism has not been altered as an effect of the added preservative.

### MEANS OF FECES ANALYSES.

It may be a matter of some interest to have a summation of all the results from the feces tests for comparison, and such summation is given in tabular form. From this it may be easily seen just how far the period results depart from the general mean.

Average composition of feces of six men during 120 days.

Subject.	Moist weight.	Dry weight.	Water.	Nitrogen.	Ether extract.	Total nitrogen.	Total ether extract.

### HIPPURIC ACID.

Because of the laborious character of the work no effort was made to carry through complete series of determinations of hippuric acid. But from time to time analyses of composites were made with the object of observing the increased output of this acid with the increase in the benzoate administered, and to find, further, whether the benzoic acid is eliminated as such, or as hippuric acid wholly. With the second object in mind more attention was given to the purity of the final extracts than to their absolute amount. In the last weeks of the preservative administration the weights of hippuric acid recovered in pure form amounted to 1.5 grams, and in some few cases to nearly 2 grams daily. In the treatment with petroleum ether for the separation of benzoic acid essentially negative results were always obtained, from which it was evident that the whole of this acid had passed over into the combined form. That this is the normal condition is now generally admitted, and calls for no further discussion here.

### NITROGEN AND FAT BALANCES.

Appended to the general urine and feces charts given in detail there are data concerning the nitrogen and fat balances for each period. The food charts, as given above, must be consulted to find the original figures from which the nitrogen and fat intake has been calculated. For purpose of ready comparison, however, it will be convenient to have all these figures in condensed tabular form. The next table presents such a condensation, the balances being calculated for the day instead of for the period, as above. It will be seen that the nitrogen balances are in most cases characteristically positive; the exceptions are so few as to have no special significance. The most marked negative balance is found in Subject No. IV, on account of the irregularities in a few meals, as referred to at the outset. For Subject No. VI we have a slight negative balance in the last period only, and for the others at earlier dates. Subjects Nos. IV and V have

small negative balances in the after period, but of trifling value. In Subject No. II a negative balance shows in the first fore period, the reason for which is not apparent.

The fat balances merely serve to show the abundant fat of the diet.

Nitrogen and fat balances.

In connection with the figures in the tables showing the consumption of food and the excretion of nitrogen two things further must be noted. The nitrogen elimination is naturally variable, but a comparison with the food charts given above will show that in general this output varies closely with the nitrogen consumption. The few exceptions to this rule do not fall in any one period of the investigation; it is therefore not possible to connect it with the presence of the benzoate in the food. The most marked of these exceptions occurs, in the case of Subject No. I, in the last preservative periods. The cause of this will be discussed under medical conditions.

### UTILIZATION OF NITROGEN AND FAT.

A study of the utilization of nitrogen and fat is instructive. The figures given above, the tables of daily means, show that the percentage amounts of fat, or crude ether extract, properly, found in the feces are variable to a high degree, but can not be connected with the benzoate addition, since the maximum values occur for the different individuals in different periods. For Subject No. I the best utilization is in the after period and the worst in the fore period. while for the high-preservative periods the utilization is nearly the same as for the after period. For Subject No. II the best utilizations are found in the last high-preservative and the after period, and distinctly better than in the fore period and the other preservative periods. For Subject No. III the utilization is good throughout, but slightly more favorable in the first high-preservative period. In the case of Subject No. IV the results for the high-preservative periods and the after period are essentially the same and very favorable. somewhat poorer utilization is found in the fore period and the lowpreservative period, which show about the same result. In Subject No. V the poorest utilization is in the fore period and the best in the after period, with that for the second high-preservative period essentially the same as for the latter. For Subject No. VI the two highpreservative periods show the most favorable results, while the least favorable are for the fore-period average. In general, there is a tendency toward good utilization extending over into the after period, which is fairly distinct in most cases.

For the utilization of nitrogen we have two considerations; we may take the relation of the nitrogen of the feces to the nitrogen of the food, or the relation of the nitrogen of the feces to the total excreted nitrogen. In either case we fail to find any systematic connection between the benzoate and the feces nitrogen. This is true, however, that the percentage of the total nitrogen excreted in the feces is always greater in the after period than in the last high-preservative period. In most cases this last high-preservative period shows the best results in this regard, but not always. The full meaning of these relations can be seen only by comparing the food tables at the same time, but it appears evident that no definite relation with the benzoate exists throughout; the utilization of nitrogen is not lessened by the addition of the preservatives.

### QUALITATIVE URINE TESTS.

In addition to the quantitative results for the urine, recited in the preceding pages, a number of special qualitative tests were regularly made. The tests for sugar, albumin, acetone, and glucoronic acid were throughout negative, and will not be tabulated. Tests

for aromatic oxyacids and for indolacetic acid were made twice a week for each subject, by the addition of Millon's reagent in the one case and of hydrochloric acid and potassium nitrite in the other to the ether extract of the urine, prepared in the usual way. From the depth of color obtained in each case the results are reported as "slight," "moderate," or "strong." It will be noticed that the data as tabulated in tables following vary in an irregular manner, and seem to show no sharp change with the increase of benzoate in the diet. One point only need be specially mentioned. In the earlier weeks of the investigation the indolacetic acid test was frequently negative in some of the men, to turn later to positive without the addition of nitrite. In all the later tests the addition of nitrite was required to complete the test. But the behavior is not general, and we have no corresponding change in the after period. It would be difficult, therefore, to connect the phenomena in any satisfactory way with the preservative.

### SEDIMENTS FROM THE URINES.

Weekly examinations of the sediments from the urines, obtained by use of the centrifuge, were made for each man. The results are given in tabular form. No characteristic variations are apparent, and in general the crystals and organized forms found in the fore periods continue throughout the whole series of tests. This is particularly true of the hyalin casts, which are frequently found in the urine of two of the men, in small numbers. At one time such casts were usually described as pathological, but it is now known that their occurrence in normal urine is by no means rare. In the numbers found in these centrifuged urines there is nothing pathological, and in any event the frequency with which they occur is not increased as the administration of benzoate begins and continues. The pus cells found rather commonly throughout in two of the cases are doubtless due to chronic gonorrhea, contracted before going on the squad. They have no bearing on the results.

[Systematic tests were made for albumin, sugar, and acetone. As these tests were uniformly negative, the results are not tabulated. The results of tests for aromatic oxygcids and indolacetic acid are given in the table below.] Qualitative urine examination.

### EXAMINATION OF THE FECES.

The above tables present all of the routine examinations carried out on the urine. We have next to consider work on the feces, which may have a bearing on the question of the possible effects of sodium benzoate on the metabolism. This work is presented in two sets of tables. The first set to follow give the results of general tests and observations, covering questions of color, reaction, consistence, odor, specific gravity as shown by rising or sinking in water, the presence of mucus, the presence of indol, the presence of biliary derivatives reacting with mercuric chloride, and finally the amount of gas liberated by bacteria present from glucose tubes and from bouillon tubes. These data are all presented in very brief form, and, in general, it will be noticed that no definite changes of any kind occur which may be associated with the benzoate added to the food. The general character of the feces seems independent of any such influence.

Following these general tables we have a more extensive series showing the results of the Gram-stain tests on the feces direct, on the sediment from the glucose tubes, and on the sediment from the bouillon tubes. As the results of these tests are rather fully given they speak for themselves, and need no additional explanation at this point. The general conclusion to be drawn from them is that the administration of benzoate in the large and small doses given in our tests has no discernible effect on the bacterial flora. While great variations in the pictures may be noticed, they occur apparently at random in the feces of the different individuals, and any sufficient evidence to connect them with the dosage appears to be quite lacking.

General character of feees.

### Results of Gram-stain tests on feces.

SUBJECT I (H. N. B.).

Date.	Gram stain direct.	Gram stain of glucose tube sediment.	Gram stain of bouillon tube sediment.
1908. July 2	Gram negative predominate. These are colon type and some rather long threads. Positive: Good many medium-sized diplococci, some large coccal bodies; some large bacilli of bacillus aerogenes capsulatus type, but shorter, some bacilli of colon morphology; some short thick bacilli with central spores (subtilis?); here and there slender curved bacilli with pointed ends.	Very few Gram negative. These of colon type. Positive: Majority are diplococci, some of which are in short chains; some bacilli of colon morphology; some very long slender bacilli in chains.	Very few Gram negative Positive: Very many of Bacillus sublilis type with central spores; many of colon morphology, and some of same shape but longer; some very long slender bacilli; here and there some free spores.
July 6	Gram negative predominate. These are of colon type and some bacilli much longer. Positive: Many bacilli of colon morphology; good many thick bacilli of medium length and of aerogenes length or longer; few bacilli slightly longer than colon bacillus, slightly bent and pointed at ends; good many large coccal and diplocal	Practically gram positive field. Majority are diplococci in chains and singly; few bacilli of colon morphology.	Almost pure culture of gram positive bacilli of the morphology of colon, except longer. A few short stout bacilli. A few bacilli of subtilis type, with central spores. Here and there some free spores.
July 9	bodies; few medium-sized diplococe. Gram positive and negative about equal. Positive: Good many large coceal and diploccal bodies; many medium-sized diplococci; some colon-like bacilli; good many slender, rather long bacilli; here and there a bacillus of subtilis type with central spore.	Practically Gram positive field: Many diplo- cocci in chains and sin- gly; many bacilli of about aerogenes cap- sulatus type, and some much shorter and some longer than these.	Almost exclusively gram positive: Almost pure culture of diplococci in chains and scattered; some bacilli of colon morphology and some longer than colon, but of same thickness.
July 13	Gram negative predominate. These are of colon type, some longer, some spirochete-like bodies, and some long, slender threads. Positive: Good many large coccal bodies; many mediumsized diplococci; here and there some bacilli of about aerogenes capsulatus type; many bacilli of colon morphology, and some longer and more siender than these.	Gram positive almost exclusively: A bundant diplococci, many in chains; few short bacilli of colon morphology.	Gram positive field; Many diplococci of medium size; many bacilli of colon morphology, and some longer than these; few free spores; here and there a siender bacillus with oval terminal spore.
July 16	Gram negative: Spirilla in small numbers and some of colon morphology. Positive: Many large coccal bodies; many medium-sized diplococci; many bacilli of colon morphology and some longer than these and curved; some bacilli approximating aerogenes in morphology; here and there bacilli with central spores.	Gram positive field: Abundant diplococci, some in chains; many bacilli of colon mor- phology; some bacilli approximating Bacil- bus a rogenes capsula- tus type, but shorter.	Practically Gram positive field: Many cocci in pairs and in chains; many ba- cilli of colon morphology; many bacilli slightly longer than the colon, slender and slightly curved; some bacilli of about aerogenes morph-
July 20	Grain positive predominating. Negatives are slender spiral and some bacilli of colon morphology. Positive: Many large coccal bodies; many medium-sized diplococci; some bacilli of about aerogenes morphology, but mostly shorter or longer than typical; many bacilli of colon morphology, and some longer than these and slightly curved; here and there bacilli with central spores.	Gram positive exclusively: Medium-sized diplococci, some in chains predominate, some bacilli of about colon morphology; some bacilli of about aerogenes morphology but longer or shorter than typical aerogenes	ology, but shorter. Positive field: Abundant medium-sized diplococci; many bacilli of colon morphology, and some longer than colon and slightly curved; some bacilli slightly shorter than aerogenes.
July 23	Gram positive predominating. Negatives are spiral organisms and bacilli of colon type. Positive: Many large coccal bodies; many clumps of and scattered diplococci; some bacilli of colon morphology, and some longer, slightly curved, a few with pointed ends; some of about aerogenes type, but shorter or longer.	genes. Positive field: Diplococci in great numbers, some in chains, some bacilli of colon length, but stouter; some bacilli of about aerogenes type, but shorter.	Positive field: Many bacill- of about colon morpholi ogy and many of same thickness, but longer; some bacilli of aerogenes capsulatus type; some medium-sized diplococci.
July 27	Gram positive and negative about equal. Negatives are spiral organisms, some of colon type and a few long threads. Positive: Some large coccal bodies; many medium-sized diplococcei; some bacilli of colon morphology and some longer than these; here and there bacillus of about aerogenes type, but shorter or longer.	Very few Gram negative. These are long slender organisms. Positive: Few diplococci of mediu a size; many hacilli of foclon length but stouter than colon; hereand the restout bacilli of about aerogenes type, but longer or shorter than typical.	Positive: Many diplococci of medium size; many bacilli of about colon morphology, but longer; some very long threads; some bacilli of colon type; a few bacilli of aerogenes type.

### Results of Gram-stain tests on feecs—Continued. SUBJECT I (H. N. B.) - Continued.

SUBJECT I (II. N. B.)—Continued.				
Date.	Gram stain direct.	Gram stain of glucose tube sediment.	Gram stain of boudlon tube sediment.	
1908. July 30	Mostly Gram positive. Negative: A few colon type, a few spirals, and some long threads. Positive: Some large coccal bodies; many tracdium-sized diplococci; some bacilli of colon morphology and sonse longer than these; some bacilli of aerogenes thickness, but not proper length; here and there thick health with contral some	Positive field: Many me- dium-sized diplococci; many bacilli of colon length but stouter; some bacilli approach- ing acrogenes in mor- phology.	Positive field: Many large bacilli of aerogenes mor- phology, but of varying length; many bacilli of colon morphology; good many bacilli in chains of subtilis type with central spore.	
Aug. 3	thick bacilli with central spore. Gram positive predominating. Negatives are of colon type, a few spiral organisms and some lone threads. Positive: Some large coccal bodies and diplococci; good many of colon type and longer, some of which are slightly curved and have pointed ends; some bacilli approaching morphology of aerogenescapsulatus type; a few long thick beailly with control process.	Positive field: Profusion of medium-sized dip-lococi; many bacilli of colon length, but stouter; some bacilli of about aerogenes type but shorter than typical.	Positive field; Some bacilli of colon type; a few medium-sized diplococci; some bacilli of aerogenes type; many bacilli in chains of subtilis type with central spore. (Con- tamination?); a few free spores.	
Aug. 6	thick bacilli with central spore. Graen positive predominating. Negativesarce feelon type and a few spirals. Positive: Some large coccal bodies; good many medium-sized diplococci; some bacilli of colon type and some longer than these; some bacilli of colon length, but stouter than colon; a few bacilli of aerogenes capsulatus type, and some of similar morphology, but longer.	Positive field: Very many medium-sized diplococci; some ba- cilli of colon type and someslightly longer; a few yery long, slender bacilli.	Practically gram positive field: Many bacilli of colon type and many longer than these; some medium-sized diplococci; a few very long threads; a few bacilli of aerogenes capsulatus type; a few bacilli of about subtilis morphology, some with central spores.	
Aug. 10	Gram positive predominating. Gram negatives are of colon type, some spirals and some long slender bacilli. Positive: Some large coccal and diplococcal bodies; many medium-sized diplococci; some bacilli of colon type; some longer than colon and slender; a few bacilli of aerogenes capsulatus type, but of varying length.	Positive field: Majority are diplococci, some in chains; a few bacilli of colon morphology; most of the bacilli are of aerogenescapsulatus type, but of varying length.	Majority Gram positive. Negatives are of colon type. Positive: Majority are slender medium- length bacilli; a few of colon morphology; a few of the slender medium- length bacilli have head- let extrunity; a good many bacilli of aerogenes capsulatus type; a few of bacilli subtilis type; here	
Aug. 14	Mostly Gram positive. Negatives are of colon type, a few spiral organisms and some long threads. Positive: Some large coceal and diplococcal bodies; majority are medium-sized diplococci; some bacilli of colon morphology; good many bacilli longer than colon and slender; a few of aerogenes capsulatus type; a few of subtilis (?) type.	Positive field: Majority are medium-sized dip- lococci, a few in short chains; remainder are thick bacilli varying from colon length to morphology of aero- genes.	and there free spores.  Mixed positive and negative. Negatives are of colon type and some bacilli that are rather long and slender. Positive: Majority are bacilli of aerogenes capsulatus type; many of medium length and slender; a few of colon morphology; a few medium-sized diplococci.	
Aug. 17	Majority Gram positive. Negatives are of colon morphology and some long slender bacilli. Positive: Good many large coccal bodies; good many medium-sized diplococci; some bacilli of colon morphology; good many bacilli of medium length or long and slender; a few of these have bulbed extremity; a few bacilli of aerogenes capsulatus type; a few of subtilis (?) type.	Positive field: Majority are medium-sized dip- lococci; remainder are thick bacilli, some of colon length, others about morphology of the aerogenes.	Gram positive field: Predominant organism is of colon morphology, but more slender and with somewhat pointed ends; a few of these are "punctate;" good many bacilli of colon morphology; occasional medium-sized diplococci; a few sporebearing bacilli in chains of subtilis type; here and there a long slender	
Aug. 20	Gram positive predominating. Negatives are bacilli of colon length and longer, and afewspirochete-like. Positive: A few large coccal bodies; many medium-sized diplococci; majority are bacilli of medium length and thickness, some longer; some bacilli of colon morphology; a few of subtilis morphology, one with central spore; here and there a bacillus of aerogenes capsulatus type.	Positive field: Almost exclusively medium- sized diplococci; a few bacilli that are stout and as long as or slightly longer than colon.	thread, Positive field: Mixed field of bacilli of subtilis type and bacilli-like aerogenes; many bacilli with termi- nal oval spore; a few free spores; a few medium- sized diplococci; here and there bacilli of colon mor- phology; some very long threads.	

### SUBJECT I (II. N. B.)—Continued.

Date.	Gram stain direct.	Gram stain of glucose tube sediment.	Gram stain of bouillon tube sediment.
1908. Aug. 24	About equally Gram positive and negative. Negatives are of colon type, some longer, and some spirals. Positive: A few large coccal bodies; many medium-sized diplococci; bacilli of medium-long bacilli of colon morphology; here and there bacilli of aerogenes type.	Positive field: Medium- sized diplococci pre- dominate; a few very long threads; a few ba- cilli that are stout and vary from colon length to morphology of aero- genes.	Positive field: Majority are medium-sized diplococci; some bacilli of colon mor- phology; many bacilli of medium length or longer and slender.
Aug. 27	Gype.  Gype.  Gype.  Gram positive predominate. Negatives are of colon type, some spirochete-like organisms and some rather long slender bacilli. Positive: Some rather large coccal bodies; some medium-sized diplococci; some bacilli of colon morphology; some slightly longer; a few rather stout, short, and medium length bacilli, here and there a bacillus approaching morphology of aerogenes.	Positive field: Majority are medium-sized dip- lococci; good many thick bacilli varying from colon length to morphology of aero- genes or longer; a few long thick threads.	Positive field: A few medium - sized diplococci; some bacilli of colon morphology; many long thin bacilli or threads, a few of which are partially decolorized; the predominant bacterium is a long slender bacillus, which in places seems to be partially decolorized; a few of these positive bacilli have swellings on the end.
Aug. 31	Gram positive and negative about equal. Negative are of colon morphology or longer and a few spirals. Positive: A few large coccal bodies; some medium-sized diplocoeci; some bacilli of colon morphology, and some slightly longer; some rather stout bacilli varying from length of colon to about aerogenes morphology.	Positive field: Majority are medium-sized dip- lococci; good many thick bacilli varying from the length of the colon to about aero- genes morphology.	Very few negative bacilli of colon type. Positive bacilli of colon morphology in predominance. A few medium-sized diplococci. A good many rather thick single bacilli of about medium length or of aerogenes morphology, some with central
Sept. 3	Gram positive predominate. Negative are of colon type or slightly longer. Positive: A few large coccal bodies; many medium-sized diplococci; many bacilli of colon morphology and many longer than these; very few of aerogenes type; here and there a few spores.	Positive field: Majority are medium-sized dip- lococci; remainder are thick bacilli of aero- genes type or of me- dium length; some long threads.	spores. Many free spores. Positive field: Majority are bacilli of colon type or slightly longer; good many bacilli in chains of subtilis type; a few rather thick bacilli of a bout aerogenes morphology or
Sept. 8	Gram positive in predominance, tive are of colon type or longer. Positive: A few large coccal bodies; many medium-sized diplococci; many bacilli of colon morphology; many bacilli longer and perhaps more slender than colon; a few of aerogenes type; here and there a free sporc.	Positive field: Majority are medium-sized dip- cocci; the rest are stout bacilli of aeroge- nes morphology; some long threads.	shorter. Positive field: Majority are bacilli of colon morphology or longer than colon; good many medium- sized diplococci; some very long very slender bacilli or threads; good many rather thick bacilli of aerogenes morphology or shorter, with central ova spore; a few free spores.
Sept. 11	Positive predominate. Negative of colon type. Positive: Some large coccal bodies; good many medium-sized dip- lococci; majority are of colon morphol- ogy; few of aerogenes type.	Like last examination	Good many negative bacilli of colon morphology. Positive: Many medium- sized diplococei; some of colon type; majority are rather thick bacilli of about aerogenes mor-
Sept. 15	Negative predominate. These of colon type. Positive: Some large coccal bodies; good many medium-sized diplococci; a good many bacilli of colon morphology or more slender; a few of aerogenes morphology; here and there bacilli resembling subtilis in morphology.	do	phology or shorter. Negative bacilli of colon type predominate. Posi- tive: Bacteria are ex- clusively large thick bac- illi of about aerogenes morphology, except that some of them have ter- minal spores.
Sept. 18	Like last description, except that positive and negative bacilli are about equal. A few spores also were seen here.	do	Positive predominate. Negative of colon type. Positive are thick bacilli of medium length or short, a few like aerogenes in morphology. Here and there a free spore.

SUBJECT II (W. W. C.)—Continued.

Date.	Gram stain direct.	Gram stain of glucose tube sediment,	Gram stain of bouillon tube sediment.	
1908. Oct. 2	Flora the same as last one, except there are much fewer diplococci.	Positive field: Nearly pure culture of medium-sized diplococci; few stout bacilli of varying lengths.	Few negative of colon type. Positive: Good many ba- cilli of about colon mor- phology, and some long- er thancolon; afew bacilli seen with gram positive globules or irregular stain- ing: a good many rather stout bacilli of about aero- genes "norphology," a few of which have terminal spores; few free spores; some stout long bacilli	
Oct. 6	Gram positive almost exclusively; majority are medium-sized diplococci; few large coccal bodies; few bacilli of colon morphology or somewhat longer than colon; good many bacilli approaching aerogenes morphology, but varying considerably in length.	Positive field: Practically all are medium-sized diplococi; a few stout bacilli of aerogenes morphology.	with central spore. Positive field: Almost pure culture of slender, slightly curved medium length baccili. some somewhat longer; I headlet form seen; some bacilli of color morphology; here and there some rather long stout bacilli with central	
Oct. 9	Practically all are Gram positive; majority are medium-sized diplococci; few large coccal bodies; few bacteria of colon type; some bacilli of medium length and slender; good many bacilli of aerogenes capsulafus type, some slightly more slender; some very stout long bacilli with rounded ends.	Positive field: Practically all are medium-sized diplococci; a few stout bacilli varying from medium length to long.	spores; a few free spores. Difficult to tell Gram positive from Gram negative; practically all are Gram positive; majority are medium length slender bacilli, and some longer; 1 headlet (?) seen; some of colon type; few medium-sized diplococci; few approximating acrogenes.	
Oct. 14	Few negative of colon type or slightly longer. Positive: Good many medium-sized diplococci; few large coccal bodies; good many of colon type; good many slightly longer and more slender than colon; few of aerogenes type; here and there one with spore and clostridium-like; few free spores.	Negative in predominance: these of colon type or slightly longer. Positive field equally divided between medium-sized diplococci and large stout bacilli, some approximating acrogenesmorphology, others shorter.	Few negative of colon type. Positive: Majority of colon morphology but longer; some of colon morphology; a few medium-sized diplococe; good many large bacilli of about aerogenes diameter, some of aerogenes length; others are slightly stouter and of medium length and short; some	
Oct. 16	Few negative of colon type. Positive: Some large coceal and diplococeal bodies; good many medium-sized diplococei; good many hacilit of colon type; others like colon but more slender and curved; others slightly longer than colon, but of colon thickness; some of aerogenes morphology, but more slender; few of aerogenes morphology; few bacilli very stout and very short or long.	Positive field: Practically all are medium-sized diplococci; few of aerogenes thickness, but of varying lengths, short to long; few more slender than aerogenes, but of aerogenes length.	free spores. Some negative bacilli slight- ly longer than colon, and some of colon morpholo- gy. Positive: Majority are slender, long, and me- dium length bacilli; a few of these are irregularly Gram positive, and some have swellings on end; others of this type have distinct terminal oval spores; few medium-sized	
Oct. 20	Few negative bacilli of colon morphology, some slightly more slender than colon, and some slightly longer than colon. Positive: Likelast description.	Like last description	diplococi. Positive field: Few medi- tur-sized-diplococci; good- many bacilli of colon mor- phology; good many long slender bacilli, some of which have terminal oval spores; good many long stort-bacilli with rounded ends and bulgingcenters, but no distinct central spores; here and there I	
Oct. 23	Like last description	dodo	of a rocenes morphology. Positive field: Good many medium-sized diplococci; good many long slender bacilli with terminal oval spores; majority are ba- cilli of colon morphology, some slightly longer than colon.	

SUBJECT II (W. W. C.) -Continued.

Date	Gram stain direct.	Gram stain of glucose tube sediment.	Gram stain of bouillon tube sediment.
1908. Oct. 27	Good many negative bacilli. These are of colon type. Some slaghtly longer than colon, some considerably longer and thicker than colon, and a good many slender, short, and medium length rods and spirals. Positive: Like last description.	Like last description	Good many partly negative "punctate" base illi of colon theckness, and per- haps twee colon length. Positive: Majority are ba- cilli of colon morphology and slightly longer than colon; good many bacilli more slender and much longer than colon; many bacilli of aerogenes mor- phology; good many ba- cilli more slender than aerogenes and varying in length from short to long. Majority are negative of co- lon morphology; some slightly longer, and some very long and slender. Positive: Few medium- sized diphocore; here and there one of aerogenes morphology. Good many bacilli more slender than aerogenes, but of arro- genes and of medium length. A few "punc- tate" bacilli of colon thickness, but slightly longer.
Oct. 30	Few negative of colon morphology, and some more slender and longer than colon and curved. Positive: Like last description.	Few negative of colon type, and some shelt- ly longer than colon. Positive: Like last de- scription.	

Oct. 30	Few negative of colon morphology, and some more slender and longer than colon and curved. Positive: Like last description.	Few negative of colon type, and some shelt- ly longer than colon. Positive: Like last de- scription.	phology; good many ba- cilli more slender than nerogenes and varying in length from short to long. Majority are negative of co- lon morphology; some slightly longer, and some very long and slender. Positive: Few medium- sized diphococci; here and there one of acrosenes morphology. Good many bacilli more slender than acrogenes, but of a ro- genes and of medium length. A few "punc- tate" bacilli of colon thickness, but slightly longer.
	SUBJEC	Г III (A. G.).	
1908			
July 3	Gram positive and negative about equal. Negative are of colon type, some slightly longer than colon and a few slightly longer and thicker than colon. Positive: Good many large coccal and diplococcal bodies; good many medium-sized diplococci; some bacilli of colon morphology; some slightly thicker than colon; majority are bacilli slightly longer than colon and slightly more slender; some large bacilli containing spores; few of aerogenes capsulatus type.	A few Gram negative of colon type. Positive: Almost exclusively medium-sized diplococci; a few of colon morphology; here and there bacilli of aerogenes capsulatus type; a few thicker than acrogenes and shorter like subtilis.	Gram negative predominate. These are of colon type and some longer and more slender than colon. Positive: Here and there free spores; a few medium-sized diplococci; majority are bacilli of aerogenes morphology, but of varying lengths; a good many bacilli of subtilis type. Some free spores.
July 7	Majority are Gram positive. Negative are of colon type or slightly longer than colon. Positive: A few large coceal and diplo-occal bodies; good many medium-sized diplococei, majority are bacilli slightly longer and more slender than colon; some of colon morphology; some thick bacilli varying from colon length to aerogenes morphology, mostly medium length.	Positive field: Good many medium-sized diplococci; some of colon morphology; good many chains of subtilis type (contamination); few of aerogenes capsulatus type.	Mostly Gram positive; few negative of colon type; many medium-sized dip-lococci; majority of bacilli are of colon morphology; some slightly longer than colon, but of colon diameter; many bacilli of aerogenes morphology, some with spores; a few free spores.
July 10	Few negative of colon type or slightly longer. Positive: Good many coccal and diplococcal bodies; many medium-sized diplococci; some bacilli of colon morphology; majority of bacilli are slightly longer and more slender than colon; a few of aerogenes type; few bacilli stouter and shorter than aerogenes.	Positive field: Majority are medium-sized di- plococci, some in short chains; good many ba- cilli of colon morphol- ogy, and some slightly longer than colon; few bacilli of aerogenes type.	Positive field: Many bacilli of subtilis type; a few medium-sized diplococci; some bacilli of colon mor- phology, and some slightly longer than colon.
July 14	Few negative of colon type, some more slender and a few spirals. Positive: Some large coccal bodies; many medium-sized diplococci; many slender medium length bacilli; some like these, but considerably longer; some lake these, but thicker; a few bacilli of colon morphology; some like these, but thicker; a few bacilli of aerogenes morphology.	Positive field: Some medium-sized cocci and diplococci; good many of colon length, but thicker; many bacilli of aerogenes thickness but of varying lengths.	Positive field: Some medium - sized diplococci; practically all bacteria are of colon morphology or slightly longer than colon; very few of aerogenes type.

SUBJECT III (A. G.)—Continued.

Date.	Gram stain direct.	Gram stain of glucose tube sediment.	Gram stain of bouillon tube sediment.
1908. July 17	Positive predominate. Negative are of colon type, some longer and slender, and a few spirals. Positive: Few large coccal bodies; good many mediumsized diplococci; some bacilli of colon morphology; some bacilli of colon morphology, but thicker; good many bacillislightly longer and more slender than colon, few of aerogenes type; some large thick bacilli with spores.	Positive field: Majority are small diplococci; few of colon morphol- ogy, but thicker than colon, and some ap- proaching aerogenes in morphology.	Positive field: Majority are bacill slightly longer and perhaps more slender than colon; remainder of bacilli are thicker and approach aerogenes in morphelogy; a few medium-sized diplococci.
July 21	Few negative of colon type and some spirals. Positive: Like last description.	Positive field: Majority are medium-sized dip- lococci; some thick bacilli, some of colon length, others ap- proaching morphology of aerogenes; a few rather large coccal bodies.	Positive field: Many medium - sized diplococci; majority are bacilli of colon length, but thicker than colon; a few bacilli approaching aerogenes in morphology, but of varying length, mostly of medium length.
July 24	Few negative of colon type and some spirals. Positive: Good many large coccal bodies; many medium-sized diplococci; some bacilli of colon type and some longer than these; some bacilli of colon length or longer, but more slender and are curved and have pointed ends; some of aerogenes morphology.	Positive field: Many medium-sized diplo- cocci, some in chains; some bacilli of aero- genes diameter, but of about colon length, others slightly shorter than aerogenes.	dium rengen. Positive field: Some medium - sized diplococci; many bacilli of colon morphology and many longer than colon; some very long bacilli of about aerogenes morphology.
July 28	Few negative of colon type and some spiral organisms. Positive: A few large coccal bodies; some medium-sized diplococci; some bacilli of colon morphology, but thicker, a few in short chains; good many medium length slender bacilli; some of aerogenes type; a few long threads; a few bacilli approximating subtilis in morphology.	Positive field: Majority are medium-sized dip-lococci, some in short chains; good many short thick bacilli of colon length; a few bacilli of same thickness approaching aerogenes in morphology, but of varying length, some very long.	Positive field: Some medium-sized diplococci; majority are slender bacilli of medium length or longer, a few with headlet (?); some bacilli of subtillis type in chains; a few large diplococcal bodies; a few of aerogenes type.
July 31 Aug. 4	Accident to emulsion of feces. Few negative of colon type, some slightly longer: Positive: Some large coccal and diplococcal bodies; many medium-sized diplococci; some of colon morphology and some thicker than colon. Many slender medium length bacilli; few of acrogenes type; some long threads; a few thick medium length bacilli like subtilis in morphology.	Positive field: Many medium-sized diplococci; bacilli are thick and vary in length from colon length to aerogenes morphology or longer.	Positive field: Some medium-sized diplococci; majority are slender medium length bacilli, sume are long and have headlet or very small spore on extremity; good many free spores; a few of colon morphology; few of aerogenes morphology. Here and there stout medium length bacilli with cen-
Aug. 7	Few Gram negative of colon type an 1 some slightly longer and more siender. Positive: Like last description.	Like last description	tral spore. Positive field: Good many medium-sized diplococci; some medium length slender bacilli; good many bacilli of colon morphology, but thicker; good many of colon morphology; some Lacilli of su, tilis type; a few free spores; Lere and there as bacillins of aerogenes morphology.
Aug. 11	Like last description	do	phology.  Positive field: Field full of Lucilli of aerogenes mor- phology: a few free spores; a few short thick hacilli some of which are in chains; a few medium- sized diplococci.
Aug. 14	do	do	Positive field: Field full of large thick bacilli of aerogenes capsulatus type; a few in chains of subtilis type; a few free spores; some medium-sized diplococci; a few of colon morphology and some thicker than colon.

### SUBJECT III (A. G.)—Continued.

Date,	Gram stain direct.	Gram stain of glucose tube sediment.	Gram stain of bouillon tube sediment.
1908. Aug. 18	Like last description.	Like last description	Positive field: Many bacilli of aerogenes capsulatus type; some of subtilis type; many free spores; some bacilli of colon morphology, and some slightly longer; some of colon morphology, but thicker; some colon morphology, but thicker; some
Aug. 21	div	Like last description; some very long thick threads.	Positive field: Majority are thick bacilli, s o m e of medium length, some of colon length, others of aerogenes morpholo g y; some medium-sized diplococi; a few bacilli of medium length and slen-
Aug. 25	Like last description except more of the large coccal bodies.	Like last full description .	der. Positive field: Majority are meidum-sized diplococci; some small diplococci; a few in chains of subtilis type; remainder are bacilli of aerogenes thickness, but of short or medium length.
Aug. 28	Gram positive predominate. Negative of colon type. Positive: Many medium-sized diplococci; some large coccal bodies; good many of colon morphology; good many slightly longer than colon; many rather stout bacilli, few of these of aerogenes morphology, mostly short.	Positive field: Majority are medium-sized dip- lococci; remainder are stout bacilli, very few approximating aero- genes in morphology; most of them are of colon or medium length.	Positive field: F i e l d equally divided a non g diplococci of medium size and stout bacilli, mostly of medium length, here and there one like aerogenes in morphology; a few long thick threads.
Sept. 1	Like last description, except those bacilli that are slightly longer than colon are more in evidence.	Like last examination	Like last examination, except no threads were seen.
Sept. 4	Gram positive predominate. Negative are of colon type and slightly longer, and some spirals. Positive: Some large coccal bodies; good many medium-sized diplococci; majority are bacilli of colon morphology or slightly longer than colon, some slightly curved; some rather thick bacilli, a few of which are of aerogenes morphology, others shorter; a few free spores.	Like last description	Positive field: Good many medium-sized diplococci, some of colon morphol- ogy; most of bacteria are rather thick, varying from short to aerogenes mor- phology, but most of them are of medium length.
Sept. 9	Few negative bacilli; these are of colon type and a few large thick bacilli that are partly decolorized; otherwise flora is as in last description.	do	Like last description.
Sept. 12- 13	Gram positive predominate; negative are of colon type and spirals; one large stout bacillus. Positive: A few large coccal bodies; many medium-sized diploeocci; majority are bacilli of colon morphology or longer and more slender; some stout bacilli of aerogenes morphology or shorter; a few bacilli of subtilis morphology; here and there a free soore.	Positive field: Majority are medium-sized dip- lococci; a few medium- length stout bacilli.	Positive field: Many medium - sized diplococci; many in chains; good many bacilli of colon morphology, some rather thick bacilli of acrogenes morphology or shorter.
Sept. 16	Gram positive predominate. Negative are only of colon type. Positive: A few large coccal bodies; very many medium-sized diplococci, which are predominant; good many bacilli of colon morphology, or longer and more slender; a few bacilli of about aerogenes	Picture like that of last examination.	Positive field: Medium- sized diplococci predomi- nating; some of colon type; a few long thin bacilli; good many thick bacilli of acrogenes mor- phology, others shorter or much longer.
Sept. 19- 20	morphology or shorter. Picture like last examination	Like last examination	or much longer. Positive field: Good many medium-sized diplococci; some of colon type; a few long thin bacilli and some long thin threads; good many of aerogenes mor- phology or longer or shorter; a few chains of subtilis morphology.

SUBJECT III (A. G.)—Continued.

Date.	Gram stain direct.	Gram stam of glucose tube sediment.	Gram stain of bouillon tube sediment.
1908. Sept. 23	Positive and negative about equal. Negative of colon type. Positive: Some large contail bedies: many mediators.	Positive field: Like last description.	Positive predominate: Negative of colon type. Positive: Some medium-
Sept. 26- 27	sized diplocase; some bacilli of colon morphology, so he slightly longer and curved; very few of aerogenes type.	Positive field: Practically all are medium- sized diplococci; a few rather large diplococci in chains; very few stout bacilli of varying lengths.	sized diplococci; majority are bacilli of aerogenes morphology or shorter. Positive field: Majority are bacilli of aerogenes cap- silatus type, but many are very long; consider- able number of medium- sized diplococci; some bacilli of colon mor- phology.
Sept. 30	slender threads. Picture here like last description, except that none of the very large bacilli of unknown morphology were seen.	Like last description of this sediment.	Few gram negative of colon morphology. Positive: Majority are about medium length single bacilli, some of which contain spores; a few free spores; a few free spores; a few free spores; a few free spores; a few free spores; a few free spores; a few free spores; a few free spores; a few free free free free free free free
Oct. 3-4	Picture like last examination, except that there were found some stout bacilli of medium length, a few of which contained central spores.	Positive field: Majority are medium-sized dip- lococci; a few stout ba- cilli varying from me- dium length to about aerogenes morphology.	Positive field: Majority are bacilli of colon morphol- ogy, orslightly longer and curved; good many stout long bacilli with terminal oval spores; some bacilli of aerogenes morphology.
Oct. 7	Picture exactly like that of last examination.	Picture just like last examination.	a few free spores.  Positive field: Majority are medium-sized diplococci; a few rather large diplococci in chains; many bacilli of colon morphology or longer than these; very few of aerogenes morphology.
Oct. 10-	Few Gram negative of colon type Positive: Good many medium-sized diplococci; some bacilli of colon type, and a good many longer and more slender; few of acrogenes morphology; some bacilli longer and thicker than acrogenes.	Few gram negative of colon type and some approximating aerogenes in morphology. Positive: Few medium-sized diplococci; majority are bacilli of aerogenesmorphology, but varying in length,	Few Gram negative: These of colon type. Positive: Few medium-sized dip-lococci; many slender medium-length bacilli; some like these have terminal spores; good many of colon norphology; very few of aerogenes morphology.
Oct. 14	Picture like last description	some very long. Few Gram negative. These are of the morphology of the bacilli described under gram positive. Positive: Majority are medium- sized diplococci; few bacilli approximating aerogenes in morphology, but shorter than typical.	Positive field: Good many medium-sized diplococci; some of colon morphol- ogy; some of colon mor- phology, but longer than color; a few of aerogenes morphology, but perhaps slightly narrower.
Oct. 16	Positive field: Few large coccal bodies; many medium-sized diplececei; good many of colon morphology; some like these but more slender and curved; some slightly longer than colon and more slender; few of aerogenes morphology, and a few of aerogenes length, but slightly more slender than typical.	Few negative bacilli- like those Gram posi- tive. Positive: Major- ity are medium-sized diplococci; few bacilli- of aerogenes morphol- ogy or shorter; few ba- cilli more shender than these, but of same length.	Positive field: Majority are bacilli of aerogenes thick- ness, but varying from typical length to medium length or short; good many bacilli of colon morphology, and some slightly longer; few me- dium-sized diplococci.

Date.	Gram stain direct.	Gram stain of glucose tube sediment.	Gram stain of bouillon tube sediment.
1908. Sept. 16 Sept. 16	Gram positive and negative about equal. Negative of colon type. Positive: Some large coccal bodies; some medium-sized diplococci; majority are of colon 1 pa or ion see: a few rather thick bacilli of acrogenes type; here and there one approximating subtilis in morphology; a few free spores.  Picture like that of last description	Positive field: Practically all are medium-sized diplococci; a few rather thick medium length bacilli, simulating, except in length, the aerogenes.  Positive field: Like last description, except some of these thick bacilli are very long.	Positive field: Good many bacilli of about color morphology; good many bacilli of aerogenes capsulative types some law subtills, but not in chains: a few medium-sized diplococci.  Few negative bacilli of colon type; except for the addition of a few long thin threads, same pic-
Sept. 23	Like last description. No spores; no organisms like subtilis.	Positive field: Medium- sized diplococci about in number equal to the bacilli present; these are of aerogenes mor- phology; others shorter or longer than typical	ture as last description.  Negative bacilli of colon type predominate. Pos- itive: Few medium-sized diplococci; majority of positive bacilli are thick, about aerogenes mor- phology, except that some have bulging cen- tral spores.
Sept. 20-27	Positive predominate. Negative of colon type. Positive: Good many mediumsized diplococci; few large coccal bodies; majority are bacilli of colon morphology or longer and slightly curved; a few stout and a few thin long threads; a few bacilli of aerogenes morphology; a few free spores.	Positive field: Practi- cally all are medium- sized diplococi; some large diplococci; a few bacilli approaching aerogenes in morphol- ogy.	Positive field: Practically
Sept. 30	Gram positive and negative about equal; negative of colon type; otherwise like last description.	Like last description	Positive field: Majority are medium 'length or long stout bacilli; some of aerogenes morphology; others with terminal oval or round spore; some of the latter look much like tetanus bacilli; good many slender medium length or long bacilli; a few of coion type; a few free spores.
Oct. 3-4	Picture like last examination	do	
Oct. 7	Picture like last examination, except that negative bacteria are few; these are of colon morphology and some spi- ral organisms.	Like last description, except here were found a few thick threads.	Positive field: Practically all are of colon morphol- ogy; some medium-sized diplococci; a few bacilli similar to aerogenes in
O e t . 10-11	Gram positive predominate. Negative are of colon type, a few spirals, and an occasional long slender partially decolorized bacillus. Positive: Few large coccal bodies, some medium-sized diplococci; majority are about colon morphology or slightly more slender; good many approximating aerogenes, but of varying tinckers and beartiffee wery stout medium length or long bacilli.	Positive field: Practi- cally all are medium- sized diplococci; few rather stout bacilli of varying lengths, a few of which approximate aerogenes in mor- phology.	morphology. Positive field: Good many medium-sized diplococci; majority of bacilli are about colon morphology, or more slender: few bacilli approximating aerogenes in morphology.
Oct. 14	Like last description, except more large coccal and diplococcal bodies; few bacilli approximating aerogenes; few free spores.	Positive field: Like last description except bac cilli are mostly longer than aerogenes, but of that diameter.	Positive field: Good many medium-sized diplococci, a n d some organisms which I can not be sure of, whether cocci in pairs or short bacilli; majority are rather thick bacilli of aerogenes diameter, but of various lengths, from colon length to typical acrogenes length, mostly of medium length.

# Results of Gram-stain tests on feces—Continued. SUBJECT IV (O. F. L.)-Continued.

Date.	Gram stain direct.	Gram stain of glucose tube sediment.	Gram stain of bouillon tube sediment.
1908, Oct. 17- 18	Few negative of colon morphology, oc- casional rather long bacilli of medium thickness, and a chara of spudle- shaped organisms. Festave: Fex large coccal bednes, good many medium- sized dipleceed; majority are bacilli of colon morphology, a few of which are slender and curved; some of colon morphology, but longer, some more slender than colon and longer; few of aerogenes type; few very thick, short bacilli.	Positive field: Majority are partially decolorized bacilli of colon morphology: good many medium-sized diplococci; few bacilli of aerogenes type, and a few more slender than typical.	Few negative of colon type. Positive: Good many medium-sized diplococci; many bacilli of colon morphology; few bacilli of aerogenes thickness, but varying from short to aerogenes length, mostly of medium length.
Oct. 22	Good many negative. These are of colon type, some longer than colon, and a few stenders spreas. Positive: A few lange coccal bedies; some mediansized diplococci; some bedilli of colon morphology, and some slightly longer than colon; good many like colon, but slightly longer and more slender: a few of these are slightly curved; a few of aerogenes morphology; a few more slender and shorter than aerogenes; an occasional large, thick bacillus of uncertain identity.	Positive field: Medium- sized diplococci much to predominance; some bacilli of almost actogenes thick ness and of medium length and short; here and there one of aerogenes morphology.	Few negative bacilli that are rather stout and of medium length. Positive: Good many bacilli of colon morphology; some like colon, but slightly longer, and some more slender and longer than colon; some bacilli of aerogenes morphology; good many bacilli more slender than aerogenes and varying in length, mostly of medium length; a few rather stout bacilli of subtilis or megatherium length; and the slength of subtilis or megatherium length.
25	Like last description	cally all are medium- sized diplococci; here and there a bacillus of aerogenesmorphology; a lew morestender than aerogenes and of me- dium length and short.	rium type. Positive: Majority are ba- cilli of colon morphology and slightly longer than colon; a few medium- sized diplococci; here and there short, stout bacilli almost coccal in form; oc- casional free spores.
Oct. 25	(10.	Like ast description	A few negative of colon morphology. Positive: Majority are medium-sized diplococci; some bacilli of colon morphology; good many bacilli more slender than aerogenes and of medium length; here and there a bacillus of aerogenes morphology.
	SUBJECT	V (A. M. N.),	
July 4-5	Gram negative predominate. These are of colon type or slightly more slender and longer. Positive: Some large coccal bodies; some medium-sized diplococci; some bacilli of colon morphology; good many bacilli of medium length and slender; some short, stout bacilli and a few approximating aerogenes.	Positive field: Nearly all are medium-sized dip- lococci; a few medium length, slender bacilli.	Practically all are Gram negative of colon type; a few positive bacill; these are thick bacill; mostly short, but a few of aerogenes length. Some of the latter in short chains.  Positive field; good many
July 8	Gram positive predominate. Negative are of colon type and a few rather large, thick bacilli. Positive: Good many large coccal bodies; many medium-sized diplococci; majority are medium-length and slender bacilli; some of colon morphology; a few bacilli of aerogenes morphology; here and there some large bacilli like subtilis in morphology;	Positive field: Very few medium-sized diplo- cocci: field full of thick bacilli of aerogenes morphology or longer or shorter; some very long, thick threads.	large bacilli of aerogenes type; some medium- sized cocci; some bacilli of colon morphology; ma- jority are slender, me- dium-sized bacilli.
July 11- 12	phology. Picture of field like last description, except that negative bacilli predominate; these are of colon type or somewhat longer.	Positive field: Majority medium-sized diplococci: remainder are rather stout bacilli of medium length, approximating in places aerogenes in morphology.	Majority Gram negative. These of colon type. Positive: Some rather thick bacilli, varying from short to aerogenes morphology; a few slen- der bacilli of colon length or longer; here and there a few chains of subtilis morphology; some long narrow threads.

SUBJECT V (A. M. N.)-Continued.

Date.	Gram stain direct.	Gram stain of glucose tube sediment.	Gram stain of bouillon tube sediment.
1908.			
July 15 July 18– 19	Gram positive predominate. Negative of colon type. Positive: Some large coccal bodies; good many medium-sized diplococci; good many bacilli of aetocenes type or shorter; cool many bacilli of medium length or longer and slender; here and there a bacillus of subtilis morphology.  Gram positive and negative arout equal; negative of colon type; otherwise flora as in last examination.	Positive field: Majority are medium-sized dip-lococci; many in chains; remainder are stout bacilli, mostly of medium tenerin, others short, others of aerogenes morphology. Positive field: Majority are medium-sized dip-lococci; a few rather smallcocci; somelong, thick threads; stout bacilli as in last examination.	Positive field: Some medium-sized diplococcl, a few in chains; majority are rather thick bacilli of medium length or short, or of acrogenes morphology; here and there bacilli of colon morphology. Same as last description.
July 22	Almostexclusively Gram positive; otherwise flora as in last description.	Positive field: Cocci of medium size and the stout bacilli mentioned in last examination about equally divided; some bacilli of colon morphology.	Positive field: Majority are medium length bacilli of medium thickness; good many rather thick, long bacilli having central spores, others short or of medium length; here and there free spores; a few bacilli of colon morphology.
July 25 26	Almost exclusively Gram positive. Gram neg. of colon type. Positive: Some large coccal bodies; some medium-sized diplococci; some rather thick bacilli of aerogenes type, and some shorter and of medium length; majority of the bacilli are of medium length and thickness; some of colon morphology.	Positive field: Majority are medium-sized dip-lococci; a few stout bacilli of aerogenes morphology or of medium length or short; some long, slender, and thick threads.	Positive field: Few medium-sized diplococci; majority are rather thick bacilli of medium length or short, others of aerogenes morphology; some long, thick threads.
July 29	Picture like that of last examination	Like last description of this sediment.	Positive field: Few medium - sized diplococci; some bacilli of colon morphology. Majority are large, thick bacilli of about aerogenes morphology or longer; some of these have large or small oval terminal spores.
Aug. 1-	Picture exactly like last description,	Like last description	Exactly similar to last description.
Aug. š	Gram positive and negative about equal; negative of colon type; otherwise like last description	Exactly like last description.	Few negative of colon type. Fostive: Many bacilli of medium length and thickness; good many of colon type; many long, thick bacilli of about aerogenes morphology, some of which have ter- minal oval or round spores.
Aug. 8-9	Gram positive predominate. Negative of colon type. Positive: Some large occal bodies; good many medium-sized diplococci; few bacilli of aerogenes morphology; good many bacilli of medium length, or long and slender; some long, thick threads; occasional bacilli of subtilis morphology.	Positive field: Thick ba- cilli of various length as described before in these sediments, in predominance; me- dium-sized diplococci in minority.	Positive field: Majority are medium-sized diplococci; some small diplococci; a few thick bacilli of aero- genes thickness, varying in length from short ba- cilli to very long threads
Aug. 12	Gram positive almost exclusively. Excepting the few very long, slender bacilli mentioned among the gram positive in the last description this one tallies.	Positive field: Equally divided between medium-sized diplococi and the thick bacilli of various lengths.	Positive field: Few medium-sized diplococci; some bacilli of colon morphology; majority are thick bacilli of about aerogenes morphology or much longer; some of these long organisms can be described as threads; some of these shorter bacilli have terminal spores.

	(20200000000000000000000000000000000000	. M. 14.)—Continued.	
Date.	Gram stain direct.	Gram stain of glucose tube sediment.	Gram stain of bouillon tube sediment.
1908. Aug 16	Gram positive almost exclusively. Negative of colon type. Positive: Some large coecal bodies; some medium-sized diplococci; some bacilli of about subtilis morphology; some rather thick bacilli of aerogenes type and some shorter and of medium length; majority of bacilli are of medium length and medium thickness.	Positive field: Practically all are medium- sized diplococi, some in chains; remainder are stout bacilli of varying lengths, a few approximating aerogenes in morphology.	Positive field: Majority are bacilli of about colon morphology; some more slender and of medium length or a little longer; many long, thick bacilli of aerogenes morphology, except some of them have terminal oval spores; several chains of subtilistype; some medium-
Aug. 19	Picture like last, except in addition there are some gram negative spiro- chete-like organisms, and there are relatively more of the stout bacilli ap- proximating aerogenes.		sized diplococci. Positive field: Good many medium-sized diplococci; good many of colon morphology; a fewlong, slender bacilli; here and there a short chain of subtilistype; majority are rather thick bacilli, mostly of medium length or short, others like aerogenes in morphology.
Aug. 22-	Gram positive and negative about equal. Negative are of colon morphology and some long, siender bacilli. Positive: Some large coccal bodies; a good many medium-sized diplococci; many thick bacilli of various lengths, some short, most of them medium length, some of aerogenes morphology, and some longer; a few large, stout bacilli of sub- tills morphology; some of colon type; majority are bacilli of medium length and colon thickness.	do	Like last description, ex- cept diplococci are more abundant and there are fewer of the stout bacilli approximating aerogenes in morphology.
Aug. 26	Like last description		Mixed gram positive and negative; many long thick bacilli partially decolorized. Positive: Majority are rather thick bacilli, a few showing central spores; many of these otherwise simulate aerogenes in morphology, although they are rather short; some single bacilli even stouter than the above, and look much like subtilis in morphology, although they are not in chains.
Aug. 29-30	do	do	Positive field: Majority are bacilli of medium length and thick ness; some nearly of colon morphology; a few chains of subtilis type with central spores; some rather thick bacilli of aerogenes morphology, others longer, some shorter, and a few medium-sized diplococci.
Sept. 2	Gram positive almost exclusively, otherwise like description of Aug. 22 and 23.	do	Positive field: Many bacilli of medium length and thickness, some nearly of colon morphology; great many rather thick ba- cilli, very few of aerogenes type, mostly short; some medium-sized diplococci.
Sept. 5, 6, 7.	Positive predominate. Negative are of colon type or slightly longer and slender, and a few spirochete-like organisms. Positive: Majority are slender bacilli of colon morphology or longer; some large coccal bodies; good many medium-sized diplococci; a few bacilli of aerogenes type or longer than typical; a few free spores.	do.	Few negative bacilli of colon type or longer. Positive: Good many medium - sized diplococci; some chains of subtilis morphology; some bacilli of aerogenes morphology, others shorter than these; majority are bacilli of colon morphology or slightly longer.

Date.	Gram stain direct.	Gram stain of glucose tube sediment.	Gram stain of bouillon tube sediment.
1908. July 29	Picture like that of 25th and 26th	Positive field: Two kinds of organisms; cocei and thick bacilli as on 25th and 26th; both present in about same number.	Positive field: Majority are stout bacilli; some of aerogenes morphology, others shorter; here and there some of these have central spores; few slender bacilli of medium length with terminal spore; some medium-sized diplococci; few bacilli of colon type; some chains of subtilis type.
Aug. 1, 2	Majority Gram positive; a few large coc- cal bodies; good many medium-sized diplococci; good many bacilli of about colon morphology, some slightly curved, and some longer and more slender: a few bacilli of nerogenes type, but varying in length; here and there a thick long bacillus with central spore; occasional free spores.	Positive field: Majority are medium-sized dip-lococei; some in chains; remainder are stout bacilli, some of aerogenes morphology, others shorter or much longer; some rather long threads.	Positive and negative mixed. Few negative. These are very long slender bacilli which are decolorized in places in the field and not in others. Positive: Majority are thick bacilli, some of acrogenes in or p hology, others of medium length or short; a few mediumsized diplococci.
Aug. 5	Few negative. These are of colon type or little longer. Positive: Some large coccal bodies; good many medium- sized diplococci; majority are slender bacilli longer than colon morphology, some of which are slightly curved; a few stout bacilli as on Aug. 1 and 2; a few free spores; a few large thick ba- cilli.	Positive as on Aug. 1 and 2.	sized diplococci. Positive field: Majority are of colon morphology; some bacilli in chains of subtilis type; a few dip- lococci.
Aug. 8, 9	Picture here as on Aug. 5, except more diplococci and fewer of those described as of colon type, but longer.	Positive field, as on last examination.	Positive field: Good many bacilli of colon morphol- ogy; many bacilli of colon morphology, but longer; many rather long and thick single bacilli, some with central spores; good many free spores;
Aug. 12	Few negative of colon type. Positive: Some large coccal bodies; good many medium-sized diplococci; majority are slender bacilli, longer than colon; good many of colon morphology, some of which are slightly curved; very many stout bacilli approximating aerogenes; no spores.	do	slender bacilli; good many of colon morphology; good many free spores; good many bacilli of aero- genes morphology, and others of same diameter, but of medium length or
Aug. 15, 16	Few Gram negative; these of colon type or a little longer; some large coccal bodies; many medium-sized diplococci; good many slender bacilli of colon length or longer, some slightly curved; a few stout bacilli with central spore; a few free spores; few of aerogenes morphology.	Positive field: Cocci of medium size in dip- lococcus form and large stout bacilli, some of aerogenes morphol- ogy, others shorter or longer in about equal number.	short. Positive field: Many long, slender bacilli, and many in long threads; good many of colon morphol- ogy; good many free spores; good many of aerogenes morphology, and others of same thick- ness, but shorter.
Aug. 19	Few Gram negative, these of colon type or slightly longer. Positive: Organisms are like those of last examination, except that the medium-sized diplococci are in predominance.	Positive field: Majority are medium-sized dip- lococci; few bacilli of colon morphology; few stout bacilli, some of aerogenes morphol- ogy, others shorter or much longer.	Positive field: Many bacilli of colon morphology; some rather long, slender bacilli, a few of which have terminal spores; some bacilli of aerogenes morphology; some bacilli of morphology of bacil- lus subtilis; a few me- dium-sized diplococci.
Aug. 22, 23	Description of field coincides with that of last examination.	Positive field: Majority are medium-sized dip- lococci, a few in chains; remainder are bacilli of aerogenes morphol- ogy, and some shorter or longer than these; a few long, thick threads.	num-sized diplococci. Positive field (very poor slide): Majority are medium-sized diplococci; some rather short, thick bacilli.

Oct. 22	dium length or short, a few free spores. Few negative bacilli of colon type, and slightly longer. Positive: Few large coccal bodies: some medium-sized diplococci; good many of colon morphology; a few of colon morphology; but slightly thicker; good many of colon morphology, but longer, a few of which are slightly curved; some bacilli of aerogenes type; some of about same morphology but shorter; a few long thick bacilli with occasional central spores; a few free spores; a	Positive field, equally divided between medium-sized diplococci and bacilli of aerogenes thickness but of varying lengths; majority medium, others as long as or longer than aerogenes.	Positive field: A few medium-sized diplococci: a few bacilli of colon morphology: majority are bacilli more slender than aerogenes and mostly of medium length, some short, others long; here and there very short stout bacilli; a few free spores.
Oct. 26	Negative organisms in abundance but in minority: These are of colon morphology and slightly longer, and a few bacilli long and slender and a few spirals. Positive: Organisms as in last description.	Positive field: Practically all are medium- sized diplococci; a few bacilli more slender than aerogenes and varying in length from short to very long.	Few negative of colon morphology except longer. Positive: Majority are medium - sized diplococci; good many bacilli of colon morphology but longer; a few of colon morphology. Here and there bacilli in chains of subtilis type; some free spores; few slender long bacilli with terminal oval spore; occasional bacilli of aerogenesthickness but
Oct. 29	Good many Gram negative. These are of colon type, some slightly longer, and here and there a very long slender bacillus. Positive: Few large coccal bodies; good many medium-sized diplococci; a few of colon morphology, and a few slightly longer than these; good many of colon morphology but slightly thicker than colon; some bacilli of aerogenes morphology and some shorter than aerogenes; a few long, thick bacilli of unknown identity; occasional free spores.	Like last description	shorter than aerogenes. Positive field: Good many medium-sized diplococci a few bacilli of colon mor- phology; majority of or- ganisms are of almos aerogenes thickness and of medium length or short; a few approxi- mating aerogenes in mor- phology.

# MEDICAL CONTROL.

Through the whole of the four months the men on the squad were kept under close observation by Doctor Buhlig, who, in addition to the bacteriological work just recorded, made certain routine clinical tests. Once a month a thorough examination of each subject was made by Doctor Buhlig personally, and daily clinical observations were carried out by two of the members of the squad on themselves and their colleagues. These two men were senior medical students, and their work was always done under the direction of Doctor Buhlig.

The first set of the tables following contains the results of the monthly examination. The daily records are presented next, and taken all together they give a very good picture of the general condition of the men throughout the four months. Comments will be made later on the results.

# MEDICAL REPORT.

From the data collected by Doctor Buhlig and presented in the tables just given certain conclusions may be drawn. The facts are tabulated at considerable length, which may seem unnecessary. but it has been our aim to give all the facts observed which in any way lead to a correct judgment as to the condition of the men during the period of the investigation. This very full record enables us to reach the following conclusions:

It is at once evident that no marked change of any kind has taken place in the men during the season. In all cases but one there has been a slight gain in weight over that at the beginning, which relations are shown in this way, in kilograms:

	Subject I.	Subject II.	Subject III.	Subject IV.	Subject	Subject VI.
Beginning weight. End weight. Maximum weight. Minimum weight.		68, 9 69, 5 70, 0 66, 4	72. 9 75. 2 75. 2 70. 9	66. 9 70. 4 70. 4 66. 0	73. 4   72. 5   73. 7   71. 1	82. 1 ×4. 7 84. 7 80. 0

For Subject No. I the lowest weight was reached about the middle of October, at the time when he was undergoing a severe mental strain. For the other men the minimum weights were reached in July and August, during a time of extremely hot weather. The benzoate dosage was also the lowest at this time.

# PULSE, TEMPERATURE, AND RESPIRATION.

The changes here are in general slight, without systematic variations. The exceptions are these:

No. I felt unwell on August 25 to 27 from what appeared to be an intestinal intoxication. His temperature went up to 101.8, with corresponding pulse and respiration. He suffered from headache and lumbar pains at the same time, but soon recovered.

No. IV showed a slightly elevated temperature on October 15, lasting a few hours after the evening meal; no definite symptoms.

No. V occasionally showed a temperature as high as 99.6 in the evening. On August 29 it was 100.2, but this was taken after a brisk handball game.

# BOWEL MOVEMENTS.

In general the movements were softer toward the end of the investigation than at the beginning. This was especially noticeable with No. II and No. IV, who at the start suffered sometimes from constipation. An occasional case of diarrhea was reported from the squad, but these were of short duration; the causes were usually unknown.

#### DAILY MEDICAL CONDITION.

In general this was good throughout the time of the experiments. Attention may be called to the exceptions recorded:

Subject No. I had duties connected mainly with the morgue of the school, and during the summer was obliged to handle a great deal of old dissecting material, during a general cleaning-up process. he was exposed to frequent extreme changes of temperature, which doubtless caused some of the unpleasant symptoms complained of and recorded. During the summer he had much trouble with his eves, and at the time of an examination homatropine was instilled into them. This had been done also on a former examination, and at both times he was rendered temporarily unwell. During the last part of the period of observation the subject labored much of the time under a severe nervous strain, which was finally discovered to be from anxiety on account of the condition of his mother, who was ill in a distant State. News of her death on October 15 was followed by a time of headaches and general depression on the part of the subject, which led to irregularities in appetite, suggested by some of the tables given.

Nothing unusual was noted in the general condition of Subjects II and III.

For No. IV the condition was generally good. On August 2 he had a vomiting spell, for which no cause could be discovered. On several occasions he complained of a headache which seemed to be due to attempts to dispense with his glasses.

No. V had been in generally good condition during the summer. A diarrhea reported on July 19 seemed to be due to watermelon.

No. VI must be described as in excellent condition throughout the season. The occasional presence of a little blood brought up with phlegm has no bearing on the present inquiry.

## GENERAL FECES AND URINE.

These conditions have already been commented upon. It is evident that no changes were noted here which may be attributed to the preservative employed.

## CERTAIN FURTHER DATA.

The men who served as subjects during the period of four months have all been under my observation until the time of making this report. No ill effects of any kind have been noticed in any case, and it is safe to say that they are now, and have been since the end of the experiments, in good physical condition. On December 22 a complete medical examination was made by Doctor Buhlig, which follows. It will be seen that the results of this suggest conditions which are in no wise abnormal.

During the progress of the routine observations one of the men on the squad, doing also laboratory work, A. M. N., carried out occasional tests on the urine in addition to those regularly reported. These were concerned with the so-called normal reduction of the urine—that is, the reducing power toward very sensitive ammoniacal copper solutions, which is recognized in all normal urines, but which is too slight to be quantitatively followed with the Fehling solution. About 20 tests were made on the urine of each man, beginning with the end of the last fore period and ending about the middle of the last high-preservative period. Such tests form a part of the routine work in my laboratory, and it is interesting to note that the results here obtained were in no wise different from those recorded from the normal men. While the reducing power varied from individual to individual, as is the ordinary condition, there were no systematic variations indicating any increase or decrease in this factor between the beginning of the low preservative periods and the end of the high preservative periods. The reducing powers were all within the limits accounted for by the creatinine, uric acid, and traces of carbohydrates or carbohydrate derivatives always present.

A further point must be recalled here. Two men who had been on the squad followed up the same diet under the same general conditions for a week longer, and took daily increased amounts of benzoate beginning with 5 grams and ending with 10 grams on the last day of the experiment. At the same time a third man, who had not been on the squad, but was a member of the laboratory force, had assisted in the weighing of the food, had followed essentially the same diet, and lived under the same general routine as the squad members, began with a dose of 5 grams and ended with 7.5 grams. Certain tests were made on the urines of the three men; these were for uric acid, creatinine, and normal reduction. For the two who had been under observation before, the uric acid and creatinine were found to be unchanged from the former normals. A trifling increase in the normal reduction seemed to result here, but not sharp enough to be definitely asserted. Nothing abnormal was found in the condition of the urine of the third man.

The facts of greatest importance, however, are these: The doses taken by the three men were relatively large, from the ordinary standpoint, yet no disagreeable effect of any description followed. There was no loss of appetite, no nausea, no headaches, and no intestinal disturbances which could be discerned. The men spoke of themselves as feeling perfectly well. It is true that much larger doses have been given medicinally, and for longer periods, without recorded ill effects. From the size of medicinal doses, our routine doses must be considered as small, although very large as viewed from the point of use in the preservation of food.

# GENERAL CONCLUSIONS.

In the preceding pages I have presented various kinds of data bearing on the question of the action of sodium benzoate on the human organism. In the chemical determinations on the urine and feces it was not found that any change in the normal metabolism followed; there was no alteration in the distribution of the nitrogen of the urinary constituents, and no decrease in the utilization of the protein or fat of the food. I am unable to find any alterations in the qualitative composition of the urine as shown by the various special tests made.

In the bacteriological and other tests carried out in the feces, which were extended to a considerable length, no essential change from the beginning of the fore period to the end of the high preservative period was discovered. There were fluctuations, but they were not systematic, and varied with the individuals rather than with the dosage. It is fair to conclude that the action of the benzoate, in the amounts used, on the intestinal activities or on the characteristic flora must be, at most, extremely slight.

The prolonged clinical observations recorded are intended to show clearly the actual conditions of the men from day to day. I consider them of equal importance with the chemical tests made, for the purpose of this inquiry. But one conclusion may be drawn from them, and that is that the health of the men has suffered no impairment through the use of the benzoate in the period of the observations. I believe, further, that the period is long enough to show change were it likely to occur.

In conclusion it must be said, then, that the experience in our laboratory justifies the statement that the moderate addition of sodium benzoate to our food, up to at least 1 gram daily, does not give rise to any abnormal conditions in the subject, or lead to any changes in metabolism which may be detected with the means at our command.

It follows, further, from the same observations, that such addition of benzoate to the food does not lower its value by robbing it of any element, by diminishing its digestibility, or by introducing a factor which modifies in any discoverable way the normal metabolism. The quality or strength of the food is not lowered or injuriously affected through the presence of the preservative, and this is true for large quantities as well as for small, since the amounts of preservative used in our experiments must all be considered large from the standpoint of actual use.

CHICAGO, January 15, 1909.

# THE ACTION OF SODIUM BENZOATE ON THE HUMAN BODY.

By DR. CHRISTIAN A. HERTER.

# THE ACTION OF SODIUM BENZOATE ON THE HUMAN BODY.

By Dr. Christian A. Herter.

The investigation about to be reported is one of three carried on by the United States referee board of scientific experts under a request from the Secretary of Agriculture. The investigation was planned by the referee board. The chemical work was done under the personal direction of Dr. Alfred J. Wakeman, who was assisted by the following persons: Dr. H. D. Dakin, Dr. Helen Baldwin, Samuel C. Harvey, Dr. A. I. Ringer, Dr. D. R. Lucas, E. N. O'Brien, P. S. Kober, and M. Fine. The bacteriological work on the feces was done by Dr. William R. Williams. The study of the blood and the gastric contents was carried on by Dr. J. S. Thacher, with the aid of Dr. L. R. Williams, Dr. A. C. Crump, and Miss S. Granat.

Its object, like that of the other investigations by the referee board, was to ascertain the influence of large and small doses of sodium benzoate on the human organism. The investigation naturally involved the consideration of a variety of physiological processes. In the present report these observations will be classed under the following heads:

- I. General medical notes.
- II. Analytical data relating to the urine and the feces.
- III. Fats and fat balance.
- IV. General urinary examination.
- V. Special urinary examination for benzoic acid.
- VI. Special chemical examination of the feces.
- VII. Bacteriological examination of the feces.
- VIII. Caloric values of the foodstuffs.
  - IX. Special clinical data.
  - X. Summary of conclusions from each case.
  - XI. Summary of conclusions from the entire group (four cases).
- XII. Methods of analysis and examinations.

It has been considered best to present the numerous results involved in this investigation according to the findings obtained in each experimental subject. In the present investigation four subjects were employed. It was deemed advisable to consider the results in each case under four distinct divisions corresponding to the various periods of the experiment, namely, (1) the fore period, (2) the low benzoate period, (3) the high benzoate period, and (4) the after period. The conclusions from the data relating to each case are separately stated and from these conclusions from the individual cases are derived the conclusions applicable to the entire group.

# CASE I R.

## GENERAL MEDICAL NOTES.

The subject of this experiment was a physician 25 years of age and in good health, though somewhat undernourished. During previous summers he had shown a slight tendency toward loss of weight, without any accompanying disorders of digestion. During the experiment with which we are here concerned he led an absolutely regular and normal life. He had about seven hours of sleep out of the twenty-four, took exercise daily for one or two hours (walking) and on Sundays played tennis for about two hours in the morning. He took a daily morning bath at a temperature of 20° to 25° C.

The course of the benzoate experiment was eventless in this case so far as any symptoms of deranged function are concerned. The subject remained well throughout the entire period of the experiment. There was no disorder of digestion, nor of nervous function.

The daily dose of sodium benzoate was 0.3 gram during the low benzoate period. During the high benzoate period it ranged from 0.6 gram to 6 grams per day.

# ANALYTICAL DATA RELATING TO THE URINE AND THE FECES.

Considering first the facts relating to the urine and to the feces, we may arrange these facts in their relation to the following subjects: Volume of the urine; specific gravity; total nitrogen; nitrogen balance; nitrogen of urea; nitrogen of ammonia; purin nitrogen; uric acid nitrogen: creatinin nitrogen; hippuric acid nitrogen; undetermined nitrogen; total sulphur; inorganic sulphur; ethereal sulphur; neutral sulphur; phosphorus; indican; indolacetic acid; aromatic oxyacids; chlorine; reaction of the urine. In the present connection we may consider also the following facts in regard to the feces: Weight of fresh feces: weight of dried feces; water; total nitrogen; ethereal extract.

#### THE URINE.

#### VOLUME.

The volume of the urine (Series A, I R) varied between 500 c. c. and 1,960 c. c. daily. The variations in volume were irregular throughout the periods of large and small dosage and can not be regarded as hav-

ing any significance in relation to the present question, since variations in temperature, moisture, conditions of bodily activity, etc., are sufficient to account for the differences noted, all of which must be regarded as being well within the normal limits.

# SPECIFIC GRAVITY.

The specific gravity of the urine (Series A, I R) varied from 1.017 to 1.035. Like the volume of the urine, the specific gravity can not be considered to possess any significance in relation to the present investigation, since the values obtained all lie within the limits observed for normal persons. The average high specific gravity is doubtless to be referred in part to the influence of the warm weather during which a considerable part of the investigation was carried on.

# TOTAL NITROGEN.

The total nitrogen was in general not determined daily, but the figures in the table represent the averages of groups of two or three days. In some instances the total nitrogen was determined daily. Reference to the complete analytical charts (Series A, I R, subperiods 1 to 18, inclusive) will show these details.

The observations on the urines are conveniently grouped under the various periods of the experiment, namely, the "fore period," the "low benzoate period," the "high benzoate period," and the "after period." In the interest of clearness and brevity the averages for these periods have been calculated and tabulated. Such comments on the tables as seem desirable are confined to the averages. (See Series B, showing actual values, and Series D, showing averages of percentages.) This holds true not only of total nitrogen, but also of all other analytical observations.

In Case I R (see Series B, I R) the average daily excretion of total nitrogen for the fore period was 9.64 grams; for the low benzoate period, 10.9 grams; for the high benzoate period, 12.8 grams, and for the after period, 12.3 grams. This slight rise in the high benzoate period and in the after period corresponds to an increase in the intake of nitrogenous food. (See Series F, I R.) It is desirable to note this rise in the nitrogen output, inasmuch as there is a corresponding rise in other constituents of the urine dependent on protein metabolism, namely, sulphuric and phosphoric acids.

# NITROGEN BALANCE.

The data relating to the nitrogen balance are given in a special table (Series F, I R), to which the reader is referred for details. Only the average daily nitrogen balance for the four different periods of the experiment need be considered here. The average daily nitrogen balance for the fore period was positive (i. e., the intake

exceeded the output) and equaled 2.85 grams, for the low benzoate period it was positive and equaled 1.03 grams, for the high benzoate period it was positive and equaled 1.06 grams, and for the after period it was positive and equaled 0.76 gram. There is thus for each period a small positive balance.

It may be further noted that the average daily intake of nitrogen in the food varied within very narrow limits for the different periods as follows:

	irams.
Fore period	4. 36
Low benzoate period	3. 5
High benzoate period	5.04
After period	4. 33

There is no evidence, from any data given in this table, that there was any disturbance in nitrogenous metabolism during any of the periods of this experiment.

# NITROGEN OF UREA.

An inspection of the figures contained in the column giving the actual daily excretion of urea clearly shows that these values all lie well within the limits recognized as characteristic of normal conditions. Moreover, there are no abnormal or wide variations in the relation of urea nitrogen to the total nitrogen for the different periods. The average nitrogen of urea for the fore period is 83.5 per cent of the total nitrogen (see Series D, I R); the average nitrogen of urea for the eight subperiods constituting the period of low benzoate dosage is 82.1 per cent of the total nitrogen. During the period of high benzoate dosage, taken as a whole, we have an average excretion of nitrogen of urea amounting to 84.4 per cent of the total nitrogen. For the after period the average excretion of urea nitrogen amounts to 84.5 per cent of the total nitrogen. The slightly higher averages observed for the period of large benzoate dosage and the after period as compared with the earlier periods is so small as to lack significance.

# NITROGEN OF AMMONIA.

A study of the ammonia of the urine is especially facilitated by the examination of the table relating to percentages. (Series D, I R.) The figures for the absolute amounts, unless extremely high or extremely low, lack meaning. The average nitrogen of ammonia for the fore period is seen to be 4.1 per cent of the total nitrogen; for the low benzoate period, 4 per cent; for the high benzoate period, 3.9 per cent; and for the after period, 3.6 per cent. These percentages all vary within the limits observed in normal persons on ordinary mixed diet.

Slight variations observed from day to day may be interpreted as the result of a slight difference in diet. It is known that the use of a meat diet tends to increase the percentage of nitrogen of ammonia in the urine. There is no indication, however, of an increase in the percentage of nitrogen of ammonia during either the low or the high benzoate periods. The figures showing the average daily amounts of nitrogen of ammonia excreted during the various periods of the experiment are as follows (Series B, I R): For the fore period, 0.40 gram; for the low benzoate period, 0.44 gram; for the high benzoate period, 0.50 gram; for the after period, 0.45 gram.

# TOTAL PURIN NITROGEN.

What has been said of the nitrogen of ammonia applies equally to the purin bases. A study of the percentages, like a study of the absolute amount of nitrogen included under purin nitrogen, fails to show any significant changes either for the low or the high benzoate periods. The averages of purin nitrogen for the different periods are as follows (Series D, I R): Fore period, 1.9 per cent of the total nitrogen; low benzoate period, 1.9 per cent; high benzoate period, 1.8 per cent; after period, 2 per cent. These figures may be regarded as expressing a close uniformity in the excretion of purin nitrogen for the different periods. The subperiods also show only small variations.

## NITROGEN OF URIC ACID.

The uric acid, like the ammonia and purin bases, can be most advantageously studied in its percentage relations. (Series D, I R.) It is seen that the average nitrogen of uric acid in the four different periods of the experiment bears exactly the same relation to the total nitrogen. The average percentage of the total nitrogen for each period is 1.6. The variations for the subperiods are small. There is a slight absolute rise in the uric acid of the low and the high benzoate periods. (Series B, I R.) We may conclude that the use of sodium benzoate has been without discernible effect on the uric acid excretion.

# NITROGEN OF CREATININ.

An inspection of the column devoted to creatinin nitrogen in the table of percentages (Series D, I R) indicates only slight variations in the average percentages at the different periods. This is likewise true of the results giving the total amount of nitrogen of creatinin. (Series B, I R.) There is, however, a slight rise in the daily average of creatinin for the later periods. For the fore period the average daily excretion was 0.42 gram; for the low benzoate period, 0.46 gram; for the high benzoate period, 0.49 gram; for the after period, 0.47 gram. The slight increase of creatinin in the later periods is probably referable to the slight increase in the intake of meat proteins.

# NITROGEN OF HIPPURIC ACID.

The nitrogen of hippuric acid one would naturally expect to show an increase dependent on the administration of sodium benzoate, in accordance with the well known fact that hippuric acid is formed in the body by the pairing of benzoic acid with glycocoll and that most of the benzoic acid ingested is excreted by the kidneys in this combination. In this research hippuric acid is of interest only in so far as it represents the elimination of benzoic acid, and for this reason the figures in the tables to be alluded to represent only the benzoic acid moiety of the hippuric acid molecule. An increased excretion of hippuric acid is observable from period to period, with the increase in the administration of sodium benzoate. An instructive statement of the influence of sodium benzoate on the output of hippuric acid is seen in the table (Series E, IR) which represents the daily average of benzoic acid (calculated from the nitrogen of the hippuric acid of the urine) excreted during the fore period, the benzoate period, and the after period. The table shows also the amount of sodium benzoate ingested in the different periods expressed in terms of benzoic acid.

The essential features of this table are the following: During the low benzoate period the average daily dose of benzoic acid introduced was 0.2541 gram. The benzoic acid eliminated during the fore period was 0.3053 gram. In other words, the calculated amount excreted somewhat exceeds the actual amount taken. During the high benzoate period the daily excretion of benzoic acid for the entire period was 1.573 grams. The calculated amount of benzoic acid excreted daily during this period, after deducting the normal daily amount of the fore period, is 1.5611 grams. Here, then, there is a close correspondence between the amount of benzoic acid excreted and the amount administered.

It should be noted also that the after period of fourteen days shows an average daily benzoic acid excretion of 0.1538 gram.

# UNDETERMINED NITROGEN.

We may consider the undetermined nitrogen in terms of its relation to the total nitrogen. (Series D, I R.) During the fore period, the average percentage of undetermined nitrogen amounted to 5.6 per cent of the total nitrogen; for the low benzoate period, to 7 per cent; for the high benzoate period, to 3.9 per cent; and for the after period, to 5.5 per cent. It can not be said that these variations possess any significance in relation to the benzoic acid ingested. The considerable variations in undetermined nitrogen which are so commonly observed are explainable to some extent by the fact that the undetermined nitrogen is estimated by difference.

## TOTAL SULPHUR.

The average daily total output of sulphur excretion in the urine (Series B, I R) for the fore period was 0.710 gram; for the low benzoate period, 0.807 gram; for the high benzoate period, 0.947 gram; for the after period, 0.816 gram. As this increase for the late periods seems roughly parallel to the total nitrogen excretion, it may fairly be attributed to the increased ingestion of protein food.

# INORGANIC SULPHUR.

The average percentage (Series D, I R) of inorganic sulphur for the fore period was 78.4 per cent of the total sulphur; for the low benzoate period, 79.3 per cent; for the high benzoate period, 80.7 per cent; for the after period, 81.5 per cent. These variations are so slight as to be insignificant.

## ETHEREAL SULPHUR.

The relation of the ethereal sulphur to the total sulphur as expressed in percentages for the various periods will be found in the table of percentages. (Series D, I R.) It is more instructive to consider the ratio of inorganic and ethereal sulphur, especially if one is accustomed to gauge the intensity of putrefactive processes through the use of this ratio. It may be noted that the ratio of inorganic to ethereal sulphur for the fore period was 17.1; for the low benzoate period, 15.9; for the high benzoate period, 20.7, and for the after period, 15.3. These variations are too small to be significant. actual ratios for the different periods are all within the limits of health. It is perhaps worth while to mention that the highest ratiothat is, the least proportion of ethereal sulphur—was observed during the period of highest benzoate consumption. In other words, during the period of highest benzoate consumption there appears to have been a slight fall in intestinal putrefaction as gauged by this ratio. The rise in indican (Series A, I R) noted in the high benzoate period seems contradictory to the ratios given above, but a close correspondence is not to be expected.

# PHOSPHATE PHOSPHORUS.

The daily average excretion (Series B, I R) of phosphorus in the form of phosphate during the fore period was 0.84 gram; during the low benzoate period, 0.96 gram; during the high benzoate period, 1.21 grams; during the after period, 1.22 grams. There is here a noticeable increase of phosphorus excretion from the fore period to the low benzoate period and from the low to the high benzoate period. In a rough way the rise in phosphorus output corresponds to the rise in total nitrogen of the urine, already mentioned. The rise from the fore period to the benzoate periods can doubtless be referred to a slightly increased use of protein food.

#### INDICAN.

In this case there is a moderate rise in the intensity of the indican reactions during the high benzoate period. (Series A, I R.) This rise can perhaps be attributable to a rise in the intake of nitrogen in the food of this period—a rise reflected in the increased elimination of nitrogen of the urine. For, generally speaking, increased protein intake tends to increase protein putrefaction and thus may increase the indican reaction. But such an increased indican reaction does not necessarily follow a moderate increase in nitrogen intake such as occurred in this case in the high benzoate period. It may therefore be connected with the use of the large doses of the sodium benzoate. This point will be further discussed in the section on conclusions.

## INDOLACETIC ACID.

Frequent examinations were made for the presence of indolacetic acid. It was found to be present at all times. The reactions were commonly slight, sometimes moderately strong. There was no evidence that the color reactions for indolacetic acid in the urine were in any way influenced by the ingestion of sodium benzoate.

## AROMATIC OXYACIDS.

Frequent examinations were made for the presence of aromatic oxyacids. Color reactions were obtainable at all times during the experiment. The reactions were commonly slight, sometimes moderately strong. There was no evidence that the color reactions for the aromatic oxyacids of the urine were in any way influenced by the ingestion of sodium benzoate.

# CHLORINE AS SODIUM CHLORIDE,

The average daily excretion of chlorine calculated as sodium chloride (Series B, I R) for the fore period was 8.75 grams; for the low benzoate period, 10.1 grams; for the high benzoate period, 13.7 grams; for the after period, 11.5 grams. These amounts are rather high and correspond to a free use of salt in the dietary. The variations noted can not be regarded as having any significance in the present connection.

# REACTION.

The reaction of the urine showed a fair degree of acidity but with slight variations throughout the experiment. There was no evidence that the sodium benzoate had any effect upon the reaction.

#### THE FECES.

#### FRESH.

The average daily weight of the fresh feces during the fore period was 135.6 grams (Series B, I R); for the low benzoate period, 134.3

grams; for the high benzoate period, 120.4 grams; for the after period, 87.1 grams. These variations can not be regarded as important. It may be noted that there is an essential correspondence between the weight of the fresh feces, for the fore period and for the low benzoate period.

#### DRIED.

The weight of the dried feces for the fore period was 31.3 grams, as a daily average; for the low benzoate period, 27 grams; for the high benzoate period, 24.9 grams; for the after period, 22.5 grams.

# WATER.

The average percentage of water of the fresh feces for the fore period was 76.9 (Series B, I R); for the low benzoate period, 79.9; for the high benzoate period, 79.1; for the after period, 74.2.

# TOTAL NITROGEN.

The average total nitrogen of the dried feces for the fore period amounted to 1.83 per cent (Series F, I R); for the low benzoate period, to 1.57 per cent; for the high benzoate period, to 1.53 per cent; for the after period to 1.34 per cent. These results are well within the limits of normal variation and follow to some extent the variations of the nitrogen intake of the food.

# ETHEREAL EXTRACT.

The average daily weights of the ethereal extracts of the dried feces including the fatty acids of the soaps for the various periods were as follows (Series G, I R): For the fore period, 5.9 grams; for the low benzoate period, 5.5 grams; for the high benzoate period, 5.28 grams; for the after period, 5.33 grams.

# FAT BALANCE.

The features of the fat intake and output which call for comment are the following (Series G, I R):

(1) The daily average intake of fat.

(2) The percentage of neutral fats, free fatty acids, and fatty acids of soaps in the feces at different periods.

(3) The average percentage of total fats absorbed from the digestive tract (burned or assimilated).

The daily average intake of fat (ethereal extract) in this case was 90 grams for the fore period, 105.8 grams for the low benzoate period, 97.3 grams for the high benzoate period, and 103 grams for the after period. Thus the variations for the different periods were not wide.

The percentage in the feces of neutral fats, free fatty acids, and fatty acids of soaps for the different periods show only moderate

variations, all of which are well within the limits observed in normal persons. There is no indication that the sodium benzoate given in small doses or in large doses caused any alteration in the relative proportions of neutral fats, fatty acids, or soaps in the feces.

The average percentage of total fats absorbed from the intestine is

as follows:

	Per cent.
Fore period	. 93. 7
Low benzoate period	94.8
High benzoate period	
After period	. 94. 4

The correspondences in fat absorption in the different periods, as shown by the above figures, are close. Obviously these figures show that the degree of fat absorption has not been influenced either by small or by large doses of sodium benzoate.

# GENERAL URINARY EXAMINATION.

## ALBUMIN.

At no time in the course of the experiment could albumin be detected in the urine, even in traces. Examinations were made with great frequency and regularity.

#### SUGAR.

At no time in the course of the experiment could sugar be detected in the urine. Examinations were made with great frequency and regularity.

#### SEDIMENTS.

Calcium oxalate was frequently observed in the sediments of the urines. Urates were rarely observed. Phosphates were only occasionally noted. Casts were not observed.

Epithelial cells, leucocytes, and crystalline sediments were not noted more frequently during the benzoate periods than during the fore period and the after period.

The urines were well preserved in a cool place, were examined within twenty-four hours after being passed, and were subjected to frequent and regular microscopical examinations.

# SPECIAL URINARY EXAMINATION FOR BENZOIC ACID.

During the high benzoate period the urine was subjected to chemical procedures to detect the presence of benzoic acid or benzoates. It was impossible to detect the presence of benzoic acid in the urine. If present at all it must have existed in mere traces. This examination was conducted by Dr. H. D. Dakin.

## SPECIAL CHEMICAL EXAMINATION OF THE FECES.

The data relating to the feces, comprised under the above title, pertain to the reaction, the color, the consistence, the mercuric chloride reaction for hydrobilirubin, the p-dimethylamido-benzaldehyde reaction for indol and skatol, and the quantitative determination of hydrogen sulphide.

The reaction of the feces was sometimes acid to litmus, sometimes neutral, but generally alkaline. The reaction appears to have been

uninfluenced by the taking of sodium benzoate.

The color of the feces was usually brown, sometimes yellow, sometimes olive green. At times, owing to the ingestion of lampblack or charcoal, for purposes of demarcation, the stools were black or dark brown. The color of the feces appears to have been uninfluenced by the taking of sodium benzoate.

The consistence of the feces varied usually between normal limits. Occasionally there was a diarrheal stool. The daily variations in the water content of the feces may be found in the tables relating to Case I R, Series A. The consistence of the feces apparently bears no relation to the ingestion of sodium benzoate.

The reaction for hydrobilirubin was slight or negative during the fore period, frequently strong during the benzoate and after periods. This reaction varies so widely in health that it is difficult to attach significance to it unless it is either persistently strong or very slight or absent. The persistently slight reactions noted in the fore period, are somewhat unusual in persons in health, and this physiological variation is perhaps less common and therefore more noteworthy than the very strong reactions several times noted during the high benzoate period. It is not possible to state whether the very strong reactions noted during the high benzoate period were accidental or in some way connected with the benzoate dosage. It should be observed that the reactions noted during the low benzoate period all came within the limits observed under natural and healthful physiological conditions.

The reaction for indol was usually slight or moderate, seldom strong. The reactions for each period, considered separately, fall well within the normal limits. Indeed it may safely be stated that these color reactions indicate, for each period of the experiment, a rather unusually low intensity of indolic intestinal putrefaction. Possibly the reactions were on the whole somewhat stronger during the benzoate periods than during the fore period, but these differences are too slight to mark a definite tendency. Hence they call for no further comment here.

## HYDROGEN SULPHIDE.

Quantitative determinations were made of the hydrogen sulphide content of the feces from September 5 to the end of the experiment (Series I, I R). These observations were made with the thought that an abnormal grade of putrefaction might possibly be revealed by a rise in the hydrogen sulphide of the feces, as in some instances of intestinal disease. The figures obtained in the present instance fall well within the limits of the normal. In fact they indicate very moderate or small values of hydrogen sulphide, both in the high benzoate period and in the after period. We are thus justified in concluding that the fixation of the hydrogen sulphide in the feces in this subject was not influenced by the taking of large doses of sodium benzoate.

Note.—In addition to this chemical examination, the feces were subjected to microscopic study to determine whether there were any alterations in their character indicating a diminished absorption of foodstuffs (e. g., meat fiber, fats, etc.) during the benzoate periods. No changes of this character were detectable. Moreover no increase in mucus was observable and no increase in cellular elements (including leucocytes) derived from the intestinal wall.

# BACTERIOLOGICAL EXAMINATION OF THE FECES.

The bacteriological examination of the feces consisted of the study of the microscopical preparations of Gram-stained smears made from the feces (usually within one or two hours of their passage), of the study of the gas production in dextrose-bouillon fermentation tubes, and the study of the Gram-stained sediments obtained from these fermentation tubes. Elaborate cultural studies of the fecal bacteria were not undertaken because it was believed that the results obtainable from them would not be commensurate in value with the labor and expense involved.

# GRAM-STAINED FECAL SMEARS.

The Gram-stained fecal smears were made daily throughout the experiment. These smears were studied with a view to noting any striking differences in the morphology and staining properties of the fecal bacteria in the course of the experiment. Experience has shown that marked variations in the flora may be detectable by the examination of the Gram-stained feces. Slight variations can not, of course, be determined in this way, but it was believed that this method afforded a reasonable chance of detecting significant variations in the flora, should they arise in consequence of the use of sodium benzoate.

In Case I R the slides show moderate variations from day to day in the morphology of the bacteria and their failure or ability to take

the Gram-stain. These variations are of the same nature as those observed in all normal individuals, even when approximately the same diet is maintained (as in the present experiment). Neither the preparations belonging to the period of small dosage nor that of high dosage reveal any significant or persistent variations. preparations of bacteria which we are justified in roughly and provisionally grouping under the B. coli and B. lactis aerogenes types. the coccal type, the acidophile and B. infantilis types, and the B. aerogenes capsulatus types varied throughout the extent of the observations within limits observable in health.

# GAS PRODUCTION IN DEXTROSE-BOUILLON FERMENTATION TUBES.

Observations were made twice weekly on the gas production of the mixed fecal flora in dextrose-bouillon fermentation tubes in the hope of detecting any influence that might possibly be exerted by sodium benzoate on the gas forming function of the intestinal bacteria. Fluctuations in the quantity of gas formed in the dextrosebouillon tubes by the mixed flora from the same individual are, of course, to be expected under physiological conditions. But the changes in gas volume referable to the bacteria inoculated from day to day are not considerable so long as the diet remains unchanged in its general characters, especially as regards the proportions of carbohydrates and proteins ingested. When the diet is markedly altered with respect to proteins or carbohydrates there occurs an alteration in gas productivity on the part of the bacteria. A diet rich in protein and low in carbohydrates tends to increase the gas productivity of the fecal bacteria. A diet rich in carbohydrates and low in proteins tends to diminish the gas productivity of the fecal flora—a result exactly contrary to that which would be expected from the well-known observation that carbohydrates in abundance are apt to occasion flatulence. The reasons for this apparent paradox need not be discussed here. The important thing in this connection is that the diet of all the subjects of the experiment was fairly uniform, as may be observed from the dietary tables. Hence any considerable variations in gas production by the fecal bacteria would not be fairly attributable to variations in diet but would depend on some other cause.

The curve based on the variations of gas production by the fecal bacteria in Case I R is shown in Series K, I R. It is noteworthy that in general gas productivity is considerably lower, on the average, during the benzoate periods, than before the administration of benzoate. It should also be noted that there is a definite rise in gas production following immediately on the cessation of the high doses of sodium benzoate. The smallest gas production corresponds roughly to the largest doses of sodium benzoate.

It may be mentioned in this connection that there was a some 7hat increased use of proteins during the high benzoate period as compared with the low benzoate and the fore periods, but this would tend to increase the gas production. On the whole it seems probable that the depression in gas formation observed was an effect of the use of sodium benzoate.

# THE GRAM-STAINED FERMENTATION TUBE SEDIMENTS.

Examination of the Gram-stained sediments from the fermentation tubes indicates the presence of varieties of bacteria normally found. In general it may be said that the coccal types of bacteria, Gram-negative and Gram-positive staphylococcal forms, and sometimes diplo-streptococcal forms are more numerous in the fermentation tube sediments during the period of low gas production than during the remaining periods. It is not possible to detect in the Gram-stained smears made from the fresh feces any corresponding increase of coccal forms.

# CALORIC VALUES OF THE FOODSTUFFS.

The caloric values of the food consumed by the various subjects were computed in the following manner: From the representative samples of the food used the weight of the dried food, less the ash, was obtained. It was assumed that this food consisted of fats, proteins, and carbohydrates available for nutritive purposes. The small quantity of cellulose contained in the food does not disturb the validity of this assumption in relation to the present object. The fat of the food was calculated from the ethereal extract, the protein was calculated from the nitrogen, and the material left after deducting the fat and the nitrogen was assumed to consist of carbohydrate matter. (For further detail see under Methods; Caloric value of foods.)

In Case I R the daily average for the caloric values of the food ingested was as follows <sup>a</sup> (Series H, I R):

	Calories.
For the fore period	2, 320
For the low benzoate period	2, 252
For the high benzoate period	2, 176
For the after period	2, 311

From this it is seen that the caloric values were adequate but not excessive for a man of moderate weight following an indoor occupation calling for a moderate expenditure of muscular energy.

a Through inadvertence a record was not kept of the amount of sugar consumed with the food after August 13. The latter values in the table, especially the last two, are somewhat lower than the actual values on this account.

# SPECIAL CLINICAL DATA.

For the study of the clinical conditions in our group of cases the referee board secured the services of Dr. John S. Thacher. Doctor Thacher and his associates took charge of the medical aspects of the investigation. They also made the examinations of the blood by clinical methods, and a careful study of the gastric contents with especial reference to the free hydrochloric acid present. The specimens of blood and of gastric contents were taken for examination one hour after an Ewald test breakfast.

The results of these investigations are given in four charts in Series L. Chart No. I gives in detail all of the findings. Chart No. II gives the averages of the several determinations from specimens taken at the same time.<sup>a</sup> Chart No. III gives these same averages shown by curves. Chart No. IV gives the average figures and the composite curves obtained by averaging the results obtained from the four individuals who were the subjects of these investigations.

All of the findings except the weight and the general conditions were obtained in duplicate or multiple observations. The initial letter of the observer will be found recorded in each instance. The letters in the column at the left (Chart I) refer to the observer making determinations of hemoglobin and the collection of the specimens, the rest of the determinations being made by the observer whose initial is placed in the column at the right. All the pipettes used in the blood work were numbered, and these numbers are inserted in the first chart, so that it can be seen whether the same or different pipettes were used for different observations. The same two Fleischl hemoglobinometers were used throughout. The counting chambers used varied with the observers. One observer, "C," made one of the determinations in each examination throughout the series. The other observer, acting as a check upon the first, was changed at times. The two observers in each instance worked entirely independently.

The reader may be referred especially to Chart No. III, Series L, giving the curves showing the relative weights of the subject, the hemoglobin percentage, and the red and white cells from data derived from Chart No. II.

There are certain data relating to the clinical condition of the subjects of the benzoate experiment which are of sufficient importance, as indications of the physiological state or "state of health," to deserve special comment here. These data relate to (1) the weight of the subjects, (2) the morphological elements of the blood and the hemoglobin, (3) the hydrochloric acid of the gastric juice.

<sup>&</sup>lt;sup>a</sup> A few results relating to the leucocyte count widely at variance with the other observations on account of the development of yeast cells in one of the solutions were omitted in making the averages.

#### WEIGHT.

The weights relating to Subject I R are graphically shown in Series J, I R. The noteworthy feature in this case is the gradual rise in weight notwithstanding the ingestion of sodium benzoate. Even during the high benzoate period there is observed an increase in the body weight. (See also Series A, I R.)

# EXAMINATION OF THE BLOOD.

## HEMOGLOBIN.

The hemoglobin curve (Series L, Chart III, I R) shows uniformity throughout, with a slight tendency to rise toward the end of the experiment. There is no indication of any effect from the taking of benzoate.

# RED BLOOD CELLS.

The curve indicative of the red blood cell count shows a normal uniformity for the different periods. The slight rise during the low benzoate period does not call for discussion. No effect from the benzoate is discernible in this curve. (Series L, Chart III.)

# WHITE BLOOD CELLS.

The curve showing the numbers of the white blood cells shows a rise in the middle of the high benzoate period, which is not sustained. There is no reason to attribute this rise to the influence of the ingested benzoate. (Series L, Chart III.)

The differential lencocyte count shows only variations within normal limits. (Series L, Charts I and II.)

# FREE HYDROCHLORIC ACID.

The curve for the free hydrochloric acid of the gastric juice is of interest, as it starts from zero and gradually rises to normal values, which are attained in the high benzoate period. (Series L, Chart III.)

# SUMMARY OF CONCLUSIONS RELATIVE TO CASE I R.

In stating the conclusions derivable from this investigation relative to the action of sodium benzoate on the human body it is necessary to distinguish between the effects of small doses (under 0.5 gram daily) and the effects of large doses (over 0.5 gram daily).

# ACTION OF SMALL DOSES OF SODIUM BENZOATE.

It may be stated that no action from small doses of sodium benzoate was detectable by the methods employed in this investigation in respect to the following features:

(1) The general health of the subject, as indicated by the subjective and objective signs.

(2) The composition of the urine (with one exception, viz. the physiological effect on the hippuric acid excretion).

(3) The composition of the feces.

- (4) The absorption of fats and the fat balance.
  (5) The character of the bacteria of the intestinal tract.
  (6) The weight of the body.
  (7) The hemoglobin of the blood.
  (8) The red blood cells.

- (9) The white blood cells.

The observed rise in hippuric acid of the urine was such as to be expected from the well-known metabolism of benzoic acid in the animal organism.

# ACTION OF LARGE DOSES OF SODIUM BENZOATE.

It may be stated that no definite physiological consequences of large doses of sodium benzoate were detectable by the methods employed in this investigation, except in the following respects:

(1) There was a considerable or large rise in the hippuric acid exerction, such as would be expected from the doses of sodium ben-

zoate ingested.

- (2) There was a slight increase of the indican of the urine, which was possibly attributable to an action of the sodium benzoate—perhaps a slight irritant action in the gastro-enteric tract, so altering the secretions and bacteria as to favor intestinal putrefaction.
- (3) There was a depression of the gas-producing function of the mixed fecal bacteria in dextrose bouillon.
- (4) There was a moderate but apparently unmistakable rise in the proportion of coccal bacteria observed in the fermentation tube sediments derived from the inoculation of the mixed fecal flora.
- (5) There was a distinct rise in the free hydrochloric acid of the gastric juice.

# CASE II H.

# GENERAL MEDICAL NOTES.

The subject of this experiment was a medical student, 21 years of age, healthy, and of good habits of life. He was uncommonly well nourished, with some tendency to obesity. Twice during the course of the experiment he had slight disorders of digestion. Once there was irregularity of the bowels with some diarrhea (July 14-17) and on another occasion (August 21) colic and slight diarrhea. Investigation of these disturbances failed to connect them with the use of sodium benzoate, but made it probable that they were referable to some other influence. On September 20 the subject contracted a slight cold. With these unimportant exceptions he remained in good health throughout the course of the experiment. It should be noted that while in general a regular life was led during the experiment, there was considerable railroad travel in and out of the city. In this respect and also in respect to uniformity in food the subject of this experiment was less regular in his habits than the other members of the experimental group. It should further be observed that there was no disorder of digestion in this case during the high benzoate period. This is of interest in connection with the interpretation of the slight disorders of digestion that occurred during the low benzoate period, for if the latter were referable to the use of the benzoate it is reasonable to expect that they would recur when much larger doses of benzoate were taken. This, however, was not the case.

The daily dose of sodium benzoate was 0.45 gram for the low period; for the high benzoate period it ranged from 0.6 gram to 6 grams per day.

# ANALYTICAL DATA RELATING TO THE URINE AND THE FECES.

# THE URINE.

#### VOLUME.

The daily volume of the urine (Series A, II H) varied between 620 c. c. and 2,180 c. c. The fluctuations can be brought into no relation with the use of sodium benzoate, for during the very warm weather corresponding to a large part of the experimental period the intake of water could not accurately be measured nor could the perspiration be estimated in its volume.

#### SPECIFIC GRAVITY.

The specific gravity (Series A, II H) varied between 1.036 and 1.018, and no significance can be attached to these variations in connection with the present investigation.

# TOTAL NITROGEN.

During the fore period of fourteen days the average daily total nitrogen of the urine amounted to 13.88 grams (Series B, II H); for the low benzoate period, to 13.78 grams; for the high benzoate period, 16.04 grams; for the after period, 15.86 grams. It may be noted that the average daily nitrogen excretion for the fore period and for the low benzoate period corresponded closely.

## NITROGEN BALANCE.

The data relating to the nitrogen balance in this case are given in a special table (Series F, II II). They show for the fore period an average daily positive balance (i. e., a greater nitrogen intake than output) of 0.18 gram; for the low benzoate period a positive balance

of 1.59 grams; for the high benzoate period a negative balance of 0.6 gram; for the after period a positive balance of 1.26 grams. The daily intake of nitrogen with the food varied within small limits for the first three periods as follows:

	Grams.
Fore period	15. 5
Low benzoate period	16.8
High benzoate period	16.74
After period	18.74

There can be little doubt that the loss of nitrogen by the perspiration in this case was an element disturbing to the nitrogen balance, for the perspiration was profuse. The extent of the loss of nitrogen by the perspiration is indicated by experimental work which bears on this question.<sup>a</sup>

In our other subjects the perspiration was probably also a factor in determining the nitrogen excretion, but in this instance it is fair to assume that it was of special importance.

## NITROGEN OF UREA.

The nitrogen of urea may best be considered from the standpoint of the percentage of the total nitrogen which it represents. The average percentage of nitrogen of urea for the fore period was 80.7 per cent of the total nitrogen (Series D, II H); for the low benzoate period, 80.7 per cent; for the high benzoate period, 80.8 per cent; for the after period, 81.6 per cent. Here we have an example of close uniformity in the nitrogen of urea for the various periods of the observation, a uniformity undisturbed by the high benzoate dosage. As these percentages fall wholly within the physiological limits, their further discussion in the present connection would have no significance.

# NITROGEN OF AMMONIA.

If we look at the table for nitrogen of ammonia in this case (Series B, II H) we see that the actual excretion of nitrogen of ammonia for the fore period was 0.82 gram; for the low benzoate period, 0.76 gram; for the high benzoate period, 0.88 gram; for the after period, 0.86 gram. The average percentages of nitrogen of ammonia are as follows (Series D, II H): For the fore period, 5.9 per cent of the total nitrogen; for the low benzoate period, 5.5 per cent; for the high benzoate period, 5.5 per cent; for the after period, 5.4 per cent. There exists here a close uniformity for the various periods, both in the actual nitrogen of ammonia and in the percentages of the total nitrogen, which fall well within the limits of the normal. It is quite plain, therefore, that the use of sodium benzoate has exercised no disturbing influence on the nitrogen of ammonia.

<sup>&</sup>lt;sup>a</sup>See Atwater and Benedict, Bulletin 136, Office of Experiment Station, U. S. Department of Agriculture, 1903, p. 118.

# TOTAL PURIN NITROGEN.

The average daily output of purin nitrogen for the fore period (Series B, II II) was 0.32 gram; for the low benzoate period, 0.31 gram; for the high benzoate period, 0.34 gram; for the after period, 0.33 gram. The uniformity shown by these figures is reflected also in the percentages (Series D, II H) which show, for the fore period, an average of 2.3 per cent of the total nitrogen; for the low benzoate period, 2.3 per cent; for the high benzoate period, 2.1 per cent; for the after period, 2.1 per cent. It is unneccessary to comment on these entirely normal findings.

## NITROGEN OF URIC ACID.

The average daily excretion of uric acid nitrogen for the fore period (Series B, II II) was 0.29 gram; for the low benzoate period, 0.27 gram; for the high benzoate period, 0.29 gram; for the after period, 0.28 gram. This close uniformity for the various periods is reflected in the averages of percentages (Series D, II H), which are as follows: For the fore period, 2.1 per cent of the total nitrogen; for the low benzoate period, 2 per cent; for the high benzoate period, 1.8 per cent; for the after period, 1.8 per cent. It is safe to conclude from these entirely normal values that the administration of sodium benzoate was without appreciable influence on the excretion of uric acid.

## NITROGEN OF CREATININ.

The average daily output of nitrogen of creatinin for the fore period (Series B, II H) was 0.59 gram; for the low benzoate period, 0.67 gram; for the high benzoate period, 0.80 gram; for the after period, 0.79 gram. There is here an evident rise in the creatinin from the fore period to the two benzoate periods, this rise being maintained during the after period. It is possible that a portion of the rise may be referable to the use of sodium benzoate, it being noteworthy that the highest creatinin output corresponds to the high benzoate period. On the other hand, the rise in creatinin may be due to the moderate increase in the nitrogen intake during the high benzoate period. This appears the more probable view.

Looking at the nitrogen of creatinin from the standpoint of percentages (Series D, II H) we see only slight increase from one period to another. During the fore period the average percentage was 4.3 per cent of the total nitrogen; during the low benzoate period, 4.9 per cent; during the high benzoate period, 5 per cent; and during the after period, 5 per cent. We may, therefore, say that the rise in creatinin during the benzoate periods is noticeable also in these percentages though the change is less marked than when considered from the standpoint of actual creatinin excretion.

## NITROGEN OF HIPPURIC ACID.

The nitrogen of hippuric acid, as would be expected, rises during the benzoate periods. The table (Series E, H H) clearly shows the influence of benzoic acid intake upon the hippuric acid output for the various periods. It is seen from this table that the daily average of benzoic acid calculated from the nitrogen of the hippuric acid climinated in the urine was 0.6701 gram for the fore period; for the low benzoate period it had risen to 1.0120 grams; if we deduct from this amount, representing the daily average for the low benzoate period, the amount representing the daily average for the fore period, we get 0.3419 gram as the average daily amount of benzoic acid excreted referable to the intake of sodium benzoate during the low benzoate period. Again referring to the table, we see that the daily average amount of benzoic acid ingested during the low benzoate period was 0.3813 gram. In other words, there is here a close and satisfactory correspondence between the rise in hippuric acid output due to sodium benzoate and the actual amount of sodium benzoate ingested.

For the high benzoate period we see that the average daily amount of benzoic acid ingested was 1.5730 grams, whereas the calculated amount excreted referable to the administration of sodium benzoate amounted to 1.5689 grams. Here again we see a close and satisfactory correspondence between the actual amount of benzoate taken and the amount of hippuric acid excreted and referable to this intake.

For the after period the daily average excretion of benzoic acid amounted to 0.0546 gram.

## UNDETERMINED NITROGEN.

In regard to the undetermined nitrogen we find the daily average for the fore period amounted to 0.87 gram (Series B, II H); for the low benzoate period, 0.78 gram; for the high benzoate period, 0.75 gram; for the after period, 0.85 gram. The slightness of these variations for the different periods is reflected also in the percentages of total nitrogen (Series D, II H), the average percentage for the fore period being 6.2 per cent; for the low benzoate period, 5.7 per cent; for the high benzoate period, 4.7 per cent; for the after period, 5.4 per cent. No further comment need be made on these results, as they are obviously indicative of entirely physiological conditions which are in no wise disturbed through the use of sodium benzoate.

## TOTAL SULPHUR.

The daily average of the total output of sulphur for the fore period was 1.003 grams (Series B, II H); for the low benzoate period,

1.032 grams; for the high benzoate period, 1.173 grams; for the after period, 1.112 grams. There is thus a moderate rise in the total sulphur output from the fore period to the low benzoate period, and a still further rise from the low to the high benzoate period. During the after period there is a distinct falling off. While the total amount of sulphur in the urine in health varies in general with the total nitrogen, the correspondence is not absolute and our figures fall well within the limits of normal variation.

# INORGANIC SULPHUR.

In regard to the inorganic sulphur, we see that for the fore period the daily average output is 0.804 gram (Series B, II H); for the low benzoate period, 0.807 gram; for the high benzoate period, 0.945 gram; for the after period, 0.902 gram. The rise in inorganic sulphur from the low to the high benzoate period is distinct, as in the case of the similar rise in the total sulphur, and what has been said in relation to the latter applies also to the former. An examination of the table showing percentages (Series D, II H) indicates that the inorganic sulphur was not disturbed by the use of sodium benzoate, for during the fore period the average percentage of the inorganic sulphur was 80 per cent of the total sulphur; during the low benzoate period, 78.2 per cent; during the high benzoate period, 80.5 per cent; and during the after period 81 per cent.

# ETHEREAL SULPHUR.

The average daily excretion of ethereal sulphur for the fore period was 0.052 gram (Series B, II H); for the low benzoate period, 0.058 gram; for the high benzoate period, 0.063 gram; and for the after period, 0.052 gram. The rise from the fore period to the benzoate periods is so small that it can not be regarded as possessing any significance. Nevertheless the fall in the after period to precisely the same average level as that during the fore period is an indication that the ethereal sulphates were slightly increased during each of the benzoate periods, presumably through the slight increase in the intestinal putrefaction. The percentages (Series D, II H) relating to the ethereal sulphur simply confirm the remarks just made on the basis of the actual output of ethereal sulphur. The slight rise in ethereal sulphur during the benzoate periods is reflected also in the ratio existing between inorganic and ethereal sulphur. These changes are no greater than the fluctuations noted in health and are well within normal limits. There is no reason to ascribe them to the use of sodium benzoate.

## NEUTRAL SULPHUR.

The average daily output of neutral sulphur for the fore period was 0.147 gram (Series B. II II); for the low benzoate period, 0.167 gram;

for the high benzoate period, 0.165 gram; for the after period, 0.158 gram. These figures point to a very slight rise in the neutral sulphur during the benzoate period—a rise, however, well within the limits of the normal and probably devoid of physiological significance. The average percentages of the neutral sulphur for the fore, low benzoate, high benzoate, and after periods, are 14.9 per cent, 16.2 per cent, 14.1 per cent, and 14.3 per cent of the total sulphur (Series D, II II).

# PHOSPHATE PHOSPHORUS.

The table giving the average daily excretion of phosphorus in the form of phosphates shows an average value of 1.12 grams daily for the fore period (Series B, II II); 1.16 grams for the low benzoate period; 1.35 grams for the high benzoate period; and 1.26 grams for the after period. These slight variations in the phosphorus output for the different periods are well within the physiological limits.

# INDICAN.

There was in this case a moderate but distinct rise in the intensity of the indican reactions during the high benzoate period (Series A, II H). There is no reason to regard the rise in indican as possibly dependent on an increased intake of protein during this period, as the protein intake (see Series F, II H) was nearly uniform with the period preceding the high benzoate. Nor is there any reason to think that the increase of indican was dependent on any alteration in the quality of the protein ingested, as the diet tables do not support any such view. The possibility that the indican was increased as the result of using considerable doses of sodium benzoate must be admitted.

## INDOLACETIC ACID.

Frequent examinations were made for the presence of indolacetic acid. It was found to be present at all times. The reactions were commonly strong but hardly pathological. There was no evidence that the color reactions for indolacetic acid in the urine were in any way influenced by the ingestion of sodium benzoate.

# AROMATIC OXYACIDS.

Frequent examinations were made for the presence of aromatic oxyacids. Strong color reactions were obtainable at nearly all times during the experiment, but these reactions were hardly of pathological intensity. There was no evidence that the color reactions for aromatic oxyacids of the urine were in any way influenced by the ingestion of sodium benzoate.

# CHEORINE AS SODIUM CHEORIDE.

During the fore period the average daily excretion of chlorine (calculated as sodium chloride) was 10.2 grams (Series B, II II); during the low benzoate period, 12.7 grams; during the high benzoate period, 13.6 grams; and during the after period, 12.2 grams. The rise from the fore period to the low benzoate, the high benzoate, and the after periods, is clearly referable to increased appetite and has its explanation in a slight change in the food ingested during these periods.

#### THE FECES.

#### FRESH.

The average daily weight of the fresh feces for the fore period was 124.1 grams (Series B, II H); for the low benzoate period, 131.6 grams; for the high benzoate period, 121.1 grams; and for the after period, 116.7 grams. These variations are too small to be in any way significant, and need not be further discussed.

#### DRIFD

The average daily weight of the dried feces for the fore period was 23.6 grams; for the low benzoate period, 27.2 grams; for the high benzoate period, 28 grams; and for the after period, 25.3 grams. The slight rise in the weight of the dry feces which is observable in the benzoate periods and the after period is due to the slight increase in food which has been already mentioned.

#### WATER.

The average percentage of water of the fresh feces for the fore period was 81; for the low benzoate period, 79.3; for the high benzoate period, 76.9; and for the after period, 78.3. The variations in the water content of the feces are unimportant and require no comment.

# TOTAL NITROGEN.

The average total nitrogen of the dried feces for the fore period amounted to 1.29 per cent (Series F, II II); for the low benzoate period, to 1.41 per cent; for the high benzoate period, to 1.51 per cent; for the after period, to 1.56 per cent. These results vary with the intake of nitrogen of the food and are within the limits of normal variation.

# ETHEREAL EXTRACT.

The average daily weights of the ethereal extracts of the dried feces, including the fatty acids of the soaps, for the various periods are as follows (Series G, II H): For the fore period, 3.84 grams; for the low benzoate period, 5.50 grams; for the high benzoate period, 6.27 grams; for the after period, 6.67 grams.

### FAT BALANCE.

The features of the fat intake and output which call for comment are the same as those mentioned under Case I R, viz:

# THE DAILY AVERAGE INTAKE OF FAT.

It is noteworthy in this case that the total daily intake of fat was considerably less in the fore period than in any of the subsequent periods (Series G. H H). During the fore period the average daily intake was 100.5 grams; during the low benzoate period, 142.2 grams; during the high benzoate period, 131.4 grams; and during the after period, 151.1 grams.

THE PERCENTAGES OF NEUTRAL FATS, FREE FATTY ACIDS, AND FATTY ACIDS OF SOAPS IN THE FECES AT DIFFERENT PERIODS.

If we compare the percentages of neutral fats, free fatty acids, and fatty acids of soaps in the feces for the different experimental periods, we see that they show only moderate variations, all of which are well within the limits observed in normal persons. The variations observed are too small and too irregular to suggest that they are related to the use of sodium benzoate.

THE AVERAGE PERCENTAGE OF TOTAL FATS ABSORBED FROM THE DIGESTIVE TRACT (BURNED OR ASSIMILATED).

The average percentages of total fats absorbed from the digestive tract for the various periods were as follows: (Series G. II H.)

	Per	cent.
Fore period		96.7
Low benzoate period		96. 1
High benzoate period		95. 6
After period		95.6

The correspondence in fat absorption for the different periods is so close as to exclude the possibility of deducing from these figures any disturbing influences of the benzoate taken upon the fat absorption either during the low period or the high period.

#### GENERAL URINARY EXAMINATION.

#### ALBUMIN.

At no time in the course of the experiment could albumin be detected in the urine, even in traces. Examinations were made with great frequency and regularity.

### SUGAR.

At no time in the course of the experiment could sugar be detected in the urine. Examinations were made with great frequency and regularity.

#### SEDIMENTS.

Calcium oxalate and epithelial cells were frequently noted in the urinary sediments. Urates were rarely observed. Phosphates were frequently seen. Casts were not seen.

Epithelial cells, leucocytes, and crystalline sediments were not noted more frequently during the benzoate periods than during the

fore and after periods.

The urines were well preserved in a cool place, were examined within twenty-four hours after being passed, and were subjected to frequent and regular microscopical examinations.

# SPECIAL URINARY EXAMINATION FOR BENZOIC ACID.

During the high benzoate period the urine was subjected to chemical procedures designed to detect the presence of benzoic acid or benzoates. It was impossible to detect the presence of benzoic acid in the urine.

# SPECIAL CHEMICAL EXAMINATION OF THE FECES.

The data relating to the feces, comprised under the above title pertain to the reaction, the color, the consistence, the mercuric chloride reaction for hydrobilirubin, the p-dimethylamido-benzaldehyde reaction for indol and skatol, and the quantitative determination of hydrogen sulphide.

The reaction of the feces was sometimes acid to litmus, sometimes neutral, but generally alkaline. The reaction does not appear

to have been influenced by the ingestion of sodium benzoate.

The color of the feces was usually brown, sometimes greenish or grayish. At times, owing to the ingestion of lampblack or charcoal, for purposes of demarcation, the stools were black or very dark. The color of the feces appears to have been uninfluenced by the taking of sodium benzoate.

The consistence of the feces varied usually within normal limits. There were a few diarrheal stools. The daily variations in the water content of the feces may be found in the tables relating to Case II H, Series A. The taking of sodium benzoate apparently stands in no causal relation to the consistence of the feces.

The reaction for hydrobilirubin was usually slight and only occasionally strong. The different periods of the experiment show no distinct differences in the intensity of this reaction. There is no indication that this reaction has been in this case influenced either by the benzoate of the low period or by the benzoate of the high period.

The reaction for indol was usually slight or moderate, occasionally strong. The reactions appear to have been of about the same

average grade of intensity in all the periods, yet the record of strong reactions is somewhat more frequent for the high benzoate period than for the other periods. It must be admitted that there is a possibility that these relatively strong reactions have been in some way occasioned by the large doses of sodium benzoate. While these reactions are not of such intensity as to indicate a pathological degree of putrefaction, they may possibly be indicative of a tendency to physiological variations in an undesirable direction.

### HYDROGEN SULPHIDE.

Quantitative determinations were made of the hydrogen sulphide content of the feces from September 5 to the end of the experiment (Series I, II H). The figures obtained in the present instance fall well within the limits of the normal. They indicate only small percentages of hydrogen sulphide, both in the high benzoate period and in the after period. We are thus justified in concluding that the fixation of hydrogen sulphide in the feces in this subject was not influenced by the use of large doses of sodium benzoate.

Note.—In addition to this chemical examination, the feces were subjected to microscopic study, to determine whether there were any alterations in their character indicating a diminished absorption of foodstuffs (e. g., meat fiber, fats, etc.) during the benzoate periods. No changes of this character were detectable. Moreover, no increase in mucus was observable and no increase in cellular elements (including leucocytes) derived from the intestinal wall.

#### BACTERIOLOGICAL EXAMINATION OF THE FECES.

The bacteriological study of the feces, by the methods employed in that investigation (see corresponding section of Case I R), yielded the following results:

- (1) The feces in the benzoate periods showed no determinable changes in bacterial flora as compared with the fore period and the after period, especially no definite change in respect to organisms of the B. coli and B. lactis aerogenes types, or in respect to bacteria of the B. aerogenes capsulatus types. A definite increase in coccal types was not determinable in Gram-stained fields and plating methods were not employed in their connection.
- (2) During the high benzoate period there was an increase in the numbers of coccal organisms growing in dextrose-bouillon fermentation tubes inoculated with the mixed fecal flora. This increase in coccal forms coincided with the period in which was observed a diminution in the gas production by the mixed fecal flora.
- (3) The extent of this diminution in the gas production by the mixed fecal flora is represented in Series K, II H, which shows well the depression in gas formation incidental to the high benzoate period

and also the prompt recovery in gas production after the cessation of the benzoate.

(4) In this case the fermentation tube sediments showed frequently the presence of moderate numbers of organisms of the *B. bifidus* type. They apparently bore no relation to the benzoate intake. The presence of this type of bacteria in moderate numbers is not rare in adults, and is to be regarded as physiological.

# CALORIC VALUES OF THE FOODSTUFFS.

In Case II II the daily average for the caloric value of the food ingested was as follows: (Series H).

	Calories.
For the fore period	. 2,470
For the low benzoate period	. 3, 311
For the high benzoate period	. 3, 244
For the after period	. 3, 274

The calories for the fore period are rather low for a man of considerably more than average weight, but the caloric values of the food for the remaining periods are adequate for such a person leading an indoor life, with only moderate muscular exertion.

### SPECIAL CLINICAL DATA.

#### WEIGHT.

The variations in weight in Case II H are readily seen from the inspection of the chart (Series J, II H) where they are graphically represented. The fall in weight during the middle of July and again during the end of August is probably to be connected with the digestive disorders already mentioned. What should be especially noted is the fact that the weight of the subject rose during the high benzoate period. Taking the experimental period as a whole, it shows a distinct rise in the weight of the subject. (See also Series A, II H.)

## EXAMINATION OF THE BLOOD.

#### HEMOGLOBIN.

The hemoglobin curve (Series L, Chart III) in this case shows some irregularities, but on the whole a tendency to a rise in the hemoglobin percentage. An injurious influence from the ingestion of benzoate can not be detected.

# RED BLOOD CELLS.

The red blood cell counts show no important alterations in the various periods. The curve shows that the normal counts of the fore period are maintained throughout the experiment. No influence from the benzoate is discernible in this curve. (Series L. Chart III.)

### WHITE BLOOD CELLS.

The white blood cells show considerable fluctuations in numbers, but the variations shown by the curve fall within physiological limits. Comparing this curve with the curves from the other subjects we find no sign of any characteristic referable to the action of benzoate. (Series L. Chart III.)

The differential leucocyte count shows only variations within physiological limits. (Series L. Charts I and II.)

### FREE HYDROCHLORIC ACID.

The curve showing the course of the gastric secretion of free hydrochloric acid reveals a slight rise during the low benzoate period and a considerable rise during the high benzoate period. Comparison with similar curves from the remaining subjects indicates that this rise of hydrochloric acid in the high benzoate period was a characteristic occurrence. (Series L. Chart III.)

## SUMMARY OF CONCLUSIONS RELATIVE TO CASE II H.

In stating the conclusions derivable from this investigation relative to the action of sodium benzoate on the human body, it is necessary to distinguish between the effects of small doses (under 0.5 gram daily) and the effects of large doses (over 0.5 gram daily).

#### ACTION OF SMALL DOSES OF SODIUM BENZOATE.

It may be stated that no action from small doses of sodium benzoate was detectable by the methods employed in this investigation in respect to the following features:

(1) The general health of the subject, as indicated by the subjective and objective signs.

(2) The composition of the urine (with one exception, viz, the physiological effect on the hippuric acid excretion).

(3) The composition of the feces.
(4) The absorption of fats and the fat balance.

(5) The character of the bacteria of the intestinal tract.

(6) The weight of the body.(7) The hemoglobin of the blood.

(8) The red blood cells.

(9) The white blood cells.

The observed rise in hippuric acid of the urine was such as to be expected from the well-known metabolism of benzoic acid in the animal organism.

## ACTION OF LARGE DOSES OF SODIUM BENZOATE.

It may be stated that no definite physiological consequences of large doses of sodium benzoate were detectable by the methods employed in this investigation, except in the following respects:

(1) There was a considerable or large rise in the hippuric acid excretion, such as would be expected from the doses of sodium

benzoate ingested.

- (2) There was an increase of the indican of the urine, not great but unmistakable. This rise is possibly attributable to an action of the sodium benzoate—perhaps a slight irritant action in the gastroenteric tract, so altering the secretions and bacteria as to favor intestinal putrefaction. The behavior of the ethereal sulphates indicates that the rise in intestinal putrefaction is slight.
- (3) There was a depression of the gas-producing function of the mixed fecal bacteria in dextrose bouillon.
- (4) There was a moderate but apparently unmistakable rise in the proportion of coccal bacteria observed in the fermentation tube sediments derived from the inoculation of the mixed feeal flora.
- (5) There was a distinct rise in the free hydrochloric acid of the gastric juice.

## CASE III O.

## GENERAL MEDICAL NOTES.

The subject of this experiment, a laboratory worker, was 43 years of age, in good health, and of good and regular habits. During previous summers his weight had remained practically uniform, with only occasional slight digestive disorders. He remained in excellent condition throughout the course of the experiment, despite the fact that he was obliged to lead an unusually active and tiring life. There were no digestive or nervous disorders at any time. There was, on the contrary, some improvement in general condition toward the end of the experiment, at the time of the high benzoate period.

This case differs from cases I R and IV L in that the dosage of sodium benzoate during the low benzoate period is higher than in either of these cases, the amount of sodium benzoate taken during the low benzoate period being 0.45 gram throughout the greater part of the period, resembling in this regard Case II H. Moreover, in this case the low benzoate period, lasting fifty-three days, was immediately preceded by a period of seven days during which the subject took daily 0.6 gram of sodium benzoate. It has arbitrarily been agreed in these experiments to regard dosages under 0.5 gram as small doses, and doses of over 0.5 gram as large doses; but since the period during which 0.6 gram daily was given lasted only seven days, there

is no objection to fusing this period with the subsequent period of fifty-three days and considering the results in their entirety for this period.

# ANALYTICAL DATA RELATING TO THE URINE AND FECES.

#### THE URINE.

#### VOLUME.

The daily volume of the urine (Series A, III O) varied between 915 and 2,530 c. c. For reasons similar to those already mentioned in connection with the urinary volume in the other experimental subjects, it is not possible to attribute significance to the urinary volume in relation to the present investigation.

#### SPECIFIC GRAVITY.

The specific gravity (Series A, III O) varied between 1.016 and 1.029. The variations have no significance in relation to the present investigation.

# TOTAL NITROGEN.

The average daily total nitrogen of the urine during the fore period of thirty days amounted in this subject to 12.89 grams (Series B, III O); for the low benzoate period,<sup>a</sup> to 14.5 grams; for the high benzoate period,<sup>b</sup> to 14.95 grams; for the after period (fourteen days), to 14.28 grams. The variations in the total nitrogen in this case, therefore, are small. The slight rise observed in the benzoate and after periods is explicable by the greater amount of nitrogenous food ingested.

# NITROGEN BALANCE.

The data relating to the nitrogen balance in this case are given in table (Series F, III O). They show very narrow variations in the average daily nitrogen balance for the different periods. Thus, for the fore period we see a negative balance (i. e. a lesser nitrogen intake than output) of 0.11 gram; for the low benzoate period a negative balance of 0.26 gram; for the high benzoate period a positive balance of 0.96 gram; for the after period a positive balance of 0.24 gram.

The daily nitrogen intake with the food for the various periods is as follows:

	Grams.
Fore period	. 14 06
Low benzoate period	
High benzoate period	. 18.67
After period	. 16.66

a The length of this period, using the term in the sense mentioned above, was sixty lays.

b The duration of this period was thirty days.

There is no evidence, derivable from data given in this table, that there was any disturbance in nitrogenous metabolism during any of the periods of this experiment.

# NITROGEN OF UREA.

If we consider the nitrogen of urea in percentages of the total nitrogen, we find that the average nitrogen of urea for the fore period amounted to 79.7 per cent of the total nitrogen (Series D, III O); for the low benzoate period, to 81.9 per cent; for the high benzoate period, to 82.6 per cent; and for the after period, to 81.5 per cent. These variations are so slight that they call for no comment. They show no indication of any disturbance referable to the use of sodium benzoate.

# NITROGEN OF AMMONIA.

The daily average excretion of nitrogen of ammonia for the fore period was 0.90 gram (Series B, III O); for the low benzoate period, 0.90 gram; for the high benzoate period, 0.74 gram, and for the after period, 0.82 gram. These variations are all well within the physiological limits. Looking at the nitrogen of ammonia from the standpoint of percentages (Series D, III O) we find that for the fore period the average nitrogen of ammonia amounted to 7 per cent of the total nitrogen; for the low benzoate period, to 6.2 per cent; for the high benzoate period, 5 per cent; for the after period, 5.7 per cent. The variations here are very small, and of course lie well within the range of fluctuations observed under physiological conditions.

#### TOTAL PURIN NITROGEN.

In regard to the purin nitrogen (Series B, III O) we find for the fore period a daily average of 0.26 gram; for the low benzoate period, 0.24 gram; for the high benzoate period, 0.26 gram; for the after period, 0.25 gram. The variations are extremely small, and both these variations and the total quantities excreted fall within the limits of the normal. Regarding the purin nitrogen from the standpoint of percentages of the total nitrogen (Series D, III O) we find that for the fore period the average purin nitrogen was 2 per cent of the total nitrogen; for the low benzoate period, 1.7 per cent; for the high benzoate period, 1.8 per cent.

## NITROGEN OF URIC ACID.

The average daily excretion of nitrogen of uric acid (Series B, III O) during the fore period was 0.19 gram; during the low benzoate period, 0.20 gram; during the high benzoate period, 0.20 gram; during the after period, 0.19 gram. There is here a noteworthy degree of consistency in the uric acid excretion as expressed in the averages for the various periods. A consideration of the uric acid excretion

in terms of percentages (Series D, III O) shows the same noteworthy uniformity, for during the fore period the average uric acid nitrogen was 1.4 per cent of the total nitrogen; during the low benzoate period, 1.3 per cent; during the high benzoate period, 1.4 per cent; during the after period, 1.4 per cent.

# NITROGEN OF CREATININ.

The average daily creatinin nitrogen (Series B, III O) output during the fore period amounted to 0.45 gram; during the low benzoate period, to 0.53 gram; during the high benzoate period, to 0.59 gram; during the after period, to 0.59 gram. In terms of percentages (Series D, III O) the average creatinin nitrogen for the different periods is as follows: For the fore period, 3.5 per cent of the total nitrogen; for the low benzoate period, 3.7 per cent; for the high benzoate period, 4 per cent; for the after period, 4.2 per cent, We note, then, a slight rise in creatinin during both benzoate periods, and this rise is maintained during the after period. The slight increase is probably to be attributed to a slight increase in the intake of meat food.

## NITROGEN OF HIPPURIC ACID.

The average daily excretion of nitrogen of hippuric acid (Series B, III O) for the fore period was 0.07 gram; for the low benzoate period, 0.15 gram; for the high benzoate period, 0.33 gram; for the after period, 0.10 gram. The rise in hippuric acid is of course dependent on the intake of benzoic acid. The influence of this intake on the hippuric acid output is indicated in a special table (Series E, III O). Reference to this table shows that the benzoic acid calculated from the average daily amount of sodium benzoate ingested amounted to 0.3961 gram. The daily average increase of benzoic acid calculated from the nitrogen of the hippuric acid excreted in the urine for this same period amounted to 0.600 gram. The calculated amount is thus in excess of the actual amount ingested. This increase may be due in part to an actual increase in hippuric acid during the low benzoate period, dependent on an increased consumption of protein food. During the high benzoate period the average moiety of benzoic acid ingested amounted to 1.573 grams daily. The average daily amount calculated from the nitrogen of hippuric acid excreted for the same period, and referable to the ingested sodium benzoate is 1.86 grams. Here also there is a moderate excess in the calculated amount as compared with the quantity ingested, and this can probably be regarded as being due in part to increased intake of protein material.

# UNDETERMINED NITROGEN.

The daily average of undetermined nitrogen excreted for the fore period amounted to 0.88 gram (Series B, III O); for the low benzoate period to 0.80 gram; for the high benzoate period to 0.67 gram; for

the after period to 0.87 gram. In this case there was a fall in the undetermined nitrogen during the high benzoate period. As the undetermined nitrogen is obtained by difference, this variation, as already pointed out, possesses no significance in itself.

# TOTAL SULPHUR.

The average daily total output of sulphur for the fore period was 0.969 gram (Series B, III O); for the low benzoate period, 1.060 grams; for the high benzoate period, 1.044 grams; for the after period, 1.003 grams. The variations here are too slight to make any comment necessary.

## INORGANIC SULPHUR.

The daily average excretion of inorganic sulphur for the fore period amounted to 0.729 gram (Series B, III O); for the low benzoate period to 0.840 gram; for the high benzoate period to 0.825 gram; for the after period to 0.799 gram. If we consider these figures from the standpoint of the percentages (Series D, III O) we find that the average inorganic sulphur is as follows: For the fore period, 77.0 per cent of the total sulphur; for the low benzoate period, 79.3 per cent; for the high benzoate period, 79.1 per cent; for the after period, 79.6 per cent. There is here a noteworthy uniformity and further comment is unnecessary.

## ETHEREAL SULPHUR.

The daily averages of ethereal sulphur are as follows: For the fore period, 0.070 gram (Series B, III O); for the low benzoate period, 0.075 gram; for the high benzoate period, 0.073 gram; for the after period, 0.086 gram. The variations in ethereal sulphur are too slight to call for comment.

The ratio between inorganic and ethereal sulphur is for the fore period, 10.6 (Series D, III O); for the low benzoate period, 11.3; for the high benzoate period, 11.6; for the after period, 9.6. Looking at the matter from the standpoint of the ratios we might regard the higher ratios as pointing to a slight fall in putrefaction during the benzoate periods, but the differences are so slight that they must be considered as devoid of significance.

# NEUTRAL SULPHUR.

The average daily output of neutral sulphur for the fore period was 0.149 gram (Series B, III O); for the low benzoate period, 0.145 gram; for the high benzoate period, 0.146 gram; for the after period, 0.118 gram. The close correspondence in the output of neutral sulphur for the fore period and the benzoate periods is worthy of note.

### PHOSPHATE PHOSPHORUS.

The daily average output of phosphorus in the form of phosphates for the fore period amounted to 0.91 gram (Series B, III O); for the low benzoate period, to 1.05 grams; for the high benzoate period, to 1.04 grams; for the after period, to 1 gram. These variations are well within the normal limits.

## INDICAN.

The indican reactions in this case showed a moderate rise in their intensity during the high benzoate period (Series A, III O). As the protein intake for this period was somewhat higher than for any other period, the rise in the indican is possibly attributable to increased intestinal putrefaction due to this cause, but it is possible that the increased intensity of the reactions was in some way dependent on the high dosage with sodium benzoate.

#### INDOLACETIC ACID.

Frequent examinations were made for the presence of indolacetic acid. It was found to be present at all times. The reactions were commonly strong, but hardly pathological. There was no evidence that the color reactions for indolacetic acid in the urine were in any way influenced by the ingestion of sodium benzoate.

### AROMATIC OXYACIDS.

Frequent examinations were made for the presence of aromatic oxyacids. Strong color reactions were obtainable at nearly all times during the experiment, but these reactions were hardly of pathological intensity. There was no evidence that the color reactions for aromatic oxyacids in the urine were in any way influenced by the ingestion of sodium benzoate.

# CHLORINE AS SODIUM CHLORIDE.

During the fore period there was a daily average excretion of chlorine (calculated as sodium chloride) amounting to 11.7 grams (Series B, IIIO); for the low benzoate period, 13.5 grams; for the high benzoate period, 14.6 grams, and for the after period, 12.9 grams. A slight rise is thus observable during the benzoate periods, due to the increased use of salt with the food, and this may be regarded as an indication of somewhat increased appetite and corresponding increase in the food taken.

#### THE FECES.

# FRESH.

The weight of the fresh feces for the fore period showed a daily average of 100.6 grams (Series B, III O); for the low benzoate period, 143.2 grams; for the high benzoate period, 128.4 grams, and for the after period, 125.4 grams.

DRIED.

The dried feces showed an average daily weight of 19.4 grams for the fore period (Series B, III O); 25.6 grams for the low benzoate period; 24.9 grams for the high benzoate period, and 23.1 grams for the after period. A definite rise in the average weight of the dried feces corresponds to the increased intake of food during the benzoate periods and the after period.

## WATER.

The average percentage of water of the fresh feces for the fore period was 80.7 (Series B, III O); for the low benzoate period, 82.1; for the high benzoate period, 80.6; for the after period, 81.5.

#### TOTAL NITROGEN.

The average total nitrogen of the dried feces for the fore period amounted to 1.26 per cent (Series F, III O); for the low benzoate period, to 1.63 per cent; for the high benzoate period, to 1.62 per cent; for the after period, to 1.43 per cent. These variations are roughly parallel with the variations in the intake of nitrogen of the food.

## ETHEREAL EXTRACT.

The average daily weights of the ethereal extracts of the dried feces including the fatty acids of the soaps for the various periods were as follows (Series G, III O): For the fore period, 4.74 grams; for the low benzoate period, 6.26 grams; for the high benzoate period, 5.60 grams; for the after period, 6.50 grams.

### FAT BALANCE.

The data relating to the fat balance (Series G, III O) are less full in this case than in Case I R or Case II H, the analyses having been made for certain periods only. There is nothing noteworthy about the daily average intake of total fats for the different periods for which the data exist, the difference in the quantities being unimportant.

The percentages of neutral fats, free fatty acids, and fatty acids of soaps of the feces show no important variations for the different periods. The after period shows a rise in the percentage of free fatty acids as compared with the values for the preceding periods. This rise is at the expense of the neutral fats, to a slighter extent at the expense of the soaps. But as these variations are well within the limits of the normal they call for no comment.

If we look at the daily average of the fat absorbed, there is evident the same close correspondence for the various periods that was observable in Cases I R and II H. The figures are as follows:

		cent.
Fore period (II)		95.5
Low benzoate period (VII)		95.0
Low benzoate period (X)		94.9
High benzoate period (XIII)		94.0
High benzoate period (XV)		95.6
After period (XVII)		93.7

## GENERAL URINARY EXAMINATION.

#### ALBUMIN.

At no time in the course of the experiment could albumin be detected in the urine, even in traces. Examinations were made with great frequency and regularity.

### SUGAR.

At no time in the course of the experiment could sugar be detected in the urine. Examinations were made with great frequency and regularity.

### SEDIMENTS.

Calcium oxalate and epithelial cells were frequently noted in the urinary sediments, but not more often during the benzoate periods than during the fore and after periods. Phosphates were frequently seen; uric acid only occasionally. Casts were not observed.

The urines were well preserved in a cool place, were examined within twenty-four hours after being passed, and were subjected to frequent and regular microscopical examination.

#### SPECIAL URINARY EXAMINATION FOR BENZOIC ACID.

During the high benzoate period the urine was subjected to chemical procedures to detect the presence of benzoic acid or benzoates. It was impossible to detect the presence of benzoic acid in the urine.

## SPECIAL CHEMICAL EXAMINATION OF THE FECES.

The data relating to the feces and comprised under the above title pertain to the reaction, the color, the consistence, the mercuric chloride reaction for hydrobilirubin, the p-dimethylamido-benzaldehyde reaction for indol and skatol, and the quantitative determination of hydrogen sulphide.

The reaction of the feces was commonly alkaline to litmus, but at times acid and often neutral. The reaction does not appear to have been influenced by the ingestion of sodium benzoate.

The color of the feces was usually brown, sometimes yellow, occasionally black from lampblack used for demarcation. The color of the feces appears to have been uninfluenced by the use of sodium benzoate.

The consistence of the feces varied within normal limits. Diarrheal movements were very rare. (The daily variations in the water content of the feces may be found in the tables relating to Case III O, Series A.) The taking of sodium benzoate apparently had no effect on the consistency of the feces.

The hydrobilirubin reaction of the feces was usually slight, moderate, or negative, very rarely strong. The different periods of the experiment show no distinct differences in the intensity of this reaction. There is no indication that the reaction has been in this case influenced by the benzoate whether taken in moderate doses or larger doses.

The indol reaction was usually slight to moderately strong, seldom strong. There is no indication that the intensity of this reaction was in any way influenced by the taking of sodium benzoate, since the color reactions for the different periods show little variation.

### HYDROGEN SULPHIDE.

Quantitative determinations were made of the hydrogen sulphide of the feces from September 5 to the end of the experiment (see Series I, III O). The figures obtained in the present instance fall well within the limits of the normal. They indicate usually moderate percentages of hydrogen sulphide, seldom high percentages. We are justified in concluding that the fixation of hydrogen sulphide in the feces in this subject was not influenced by the use of large doses of sodium benzoate.

Note.—In addition to this chemical examination the feces were subjected to microscopic study to determine whether there were any alterations in their character indicating a diminished absorption of foodstuffs (e. g., meat fiber, fats, etc.) during the benzoate periods. No changes of this character were detectable. Moreover, no increase in mucus was observable and no increase in cellular elements (including leucocytes) derived from the intestinal wall.

#### BACTERIOLOGICAL EXAMINATION OF THE FECES.

The bacteriological examination of the feces was conducted along the same lines as in Case I R and Case II H. The direct study of the Gram-stained feces showed no significant variations in the flora of the intestine. Slight alterations in type occurred, but they apparently ranged within physiological limits. No changes were noted that could be brought into relation with the ingestion of sodium benzoate. On the other hand, the study of fermentation tube sediments showed an increase in the coccal types of bacteria as compared with the others. This increase in coccal forms corresponded roughly with the depression in gas formation by the mixed fecal bacteria, which was noted in this case. This depression in the gas making function of the bacteria is graphically given in Series K, III O. It is

worthy of notice that immediately after the cessation of the benzoate dosage there was a recovery of the gas forming powers of the fecal bacteria.

A further experiment was conducted with great care in this case to determine whether the depression in the gas forming function of the fecal flora was accidental or due to the sodium benzoate. The subject was kept on a very uniform diet, and while on this diet he took three grams of sodium benzoate daily. The use of sodium benzoate was again followed by a striking decline in the gas formation by the mixed fecal flora, amounting to a complete extinction of this function for a time. There was, however, a gradual recovery of this function despite the continuation of the relatively high benzoate dosage mentioned above.

In the course of the experiment efforts were made by Dr. A. I. Kendall to detect any variations in the nature of the fecal bacteria which might appear in connection with the use of sodium benzoate. Aerobic and anaerobic plate cultures were made with this end in view, but no decisive results were obtained. No evidence was found of a decline in the number of fecal bacteria of the B. coli type. On the other hand, there appeared a slight increase in the numbers of the coccal types of bacteria during the time of the benzoate dosage, but this change was not sufficiently marked to be certainly significant.

It is thus clear that large doses of sodium benzoate strongly tend to depress the ability of the fecal bacteria to form gas. The explanation of this fact is not at present clear. The depression in gas formation is certainly not due to the presence of sodium benzoate in the feces, since it was not possible to recover benzoic acid in amounts sufficient to cause such an effect. But it may be due to some action of the benzoate on the bacteria of the digestive tract at higher levels than the colon, or to an action on the digestive juices.

Whether the depression of the gas-forming function of the fecal bacteria is to be regarded as a physiological variation which is functionally desirable or undesirable or is a matter of indifference, it is impossible to state at present.

# CALORIC VALUES OF THE FOODSTUFFS.

In Case III O the daily averages for the caloric value of the food ingested were as follows (Series H, III O):

	Calories.
For the fore period	. 2,019
For the low benzoate period	. 2,763
For the high benzoate period	
For the after period	. 2,764

These caloric values are somewhat low for the fore period, but adequate in the remaining periods for a man not much above the average weight, leading an indoor life and moderately active in muscular exercise.

### SPECIAL CLINICAL DATA.

### WEIGHT.

In this case it is noticeable that there was a fall in weight during the fore period when no benzoate was taken. (Series J, III O.) The fall can reasonably be attributed to unusually prolonged and hard hours of work at the outset of the warm season. About the middle of July there developed a tendency to gain in weight and early in August this tendency became established, and is shown in the gradual but almost unbroken rise in weight during the remainder of the low benzoate period and during the entire high benzoate period. This ability of the subject to gain weight during the high benzoate period is worthy of note. There was some further gain during the after period, so that at the end of the experiment the weight approximated that at the beginning of June. Thus there was a complete recovery in weight despite distinctly adverse conditions of labor. (See also Series A, III O.)

# EXAMINATION OF THE BLOOD.

#### HEMOGLOBIN.

From the hemoglobin curve in Chart No. III (Series L) it is clear that the hemoglobin was maintained at a rather uniform level throughout the course of the experiment, with a moderate rise toward the end of the experiment. No evidence of any influence of sodium benzoate is discernible.

#### RED BLOOD CELLS

The curve for the red blood cells shows a rise for the low benzoate period, but in general rather uniform results for the entire experimental period. There is no indication of any depressing effect of the benzoate on the red blood cell count. (Series L, Chart III.)

#### WHITE BLOOD CELLS.

The curve for the white blood cells shows considerable irregularity, including a rise in the low benzoate period, followed by a drop, followed in turn by a considerable rise during the high benzoate period. Whether the benzoate had any influence in causing these irregularities must be considered doubtful in view of the absence of anything characteristic in any of the curves drawn from the four subjects and in view of the fluctuations seen in healthy individuals. (Series L, Chart III.)

The differential leucocyte count shows only variations within physiological limits. (Series L, Charts I and II.)

# FREE HYDROCHLORIC ACID.

The curve representing the free hydrochloric acid in the gastric juice shows a distinct rise during the high benzoate period, which

brings the values to a point previously reached early in the experiment. (Series L, Chart III.)

# SUMMARY OF CONCLUSIONS RELATIVE TO CASE III O.

In stating the conclusions derivable from this investigation relative to the action of sodium benzoate on the human body, it is necessary to distinguish between the effects of small doses (under 0.5 gram daily) and the effects of large doses (over 0.5 gram daily).

# ACTION OF SMALL DOSES OF SODIUM BENZOATE.

It may be stated that no action from small doses of sodium benzoate was detectable by the methods employed in this investigation in respect to the following features:

(1) The general health of the subject, as indicated by the subjective and objective signs.

(2) The composition of the urine (with one exception, viz, the physiological effect on the hippuric acid excretion).

(3) The composition of the feces.
(4) The absorption of fats and the fat balance.
(5) The character of the bacteria of the intestinal tract.
(6) The weight of the body.
(7) The hemoglobin of the blood.
(8) The red blood cells.

(9) The white blood cells.

The observed rise in hippuric acid of the urine was such as to be expected from the well-known metabolism of benzoic acid in the animal organism.

## ACTION OF LARGE DOSES OF SODIUM BENZOATE.

It may be stated that no definite physiological consequences of large doses of sodium benzoate were detectable by the methods employed in this investigation, except in the following respects:

- (1) There was a considerable or large rise in the hippuric acid excretion, such as would be expected from the doses of sodium benzoate ingested.
- (2) There was an increase of the indican of the urine, not great, but unmistakable. This rise is possibly attributable to an action of the sodium benzoate-perhaps a slight irritant action in the gastroenteric tract, so altering the secretions and bacteria as to favor intestinal putrefaction.
- (3) There was a depression of the gas-producing function of the mixed fecal bacteria in dextrose bouillon.
- (4) There was a moderate but apparently unmistakable rise in the proportion of coccal bacteria observed in the fermentation tube sediments derived from the inoculation of the mixed fecal flora.
- (5) There was a distinct rise in the free hydrochloric acid of the gastric juice.

## CASE IV L.

## GENERAL MEDICAL NOTES.

The subject of this experiment was a physician, 28 years of age, of good habits, and of good general health. His weight during previous summers had fluctuated within narrow limits without any accompanying digestive disorders. During the fortnight preceding the beginning of the benzoate experiment his weight varied between 66 and 68 kilos, the weight having spontaneously declined during this time (see graphic weight chart, Series J, IV L).

In this case considerable information was collected in relation to the composition of the urine, the chemical and bacteriological properties of the feces, etc. These observations accord closely with those

on the fore and after periods of the experiment.

It should be stated that this subject experienced discomfort, pain, and various signs of disturbed digestion after the passage of the stomach tube for purposes of gastric examination. During the first two weeks in August he complained of disturbed digestion, malaise, and inaptitude for work, which he attributed to the benzoate taken. The physicians in charge were unable to satisfy themselves that these symptoms were dependent on the benzoate ingested, but believed them to be due to other causes. The disturbances complained of were followed by an acute attack of frontal sinusitis. It should be observed that during the high benzoate period there was a gradual improvement in physical condition; on September 15 there was diarrhea, but after this time the general condition and the state of digestion were excellent.

# ANALYTICAL DATA RELATING TO THE URINE AND FECES.

#### THE URINE.

#### VOLUME.

The daily volume of urine (Series A, IV L) in this case ranged between 561 and 1,810 c. c. There is no evidence that any influence was exerted on the volume of the urine by the ingestion of sodium benzoate.

### SPECIFIC GRAVITY.

The specific gravity of the urine (Series A, IV L) varied between 1.019 and 1.036, and the variations can not be brought into relation with the ingestion of sodium benzoate.

### TOTAL NITROGEN.

In this case the average daily output of total nitrogen for the fore period amounted to 16.55 grams (Series B, IVL); for the low benzoate period, to 13.63 grams; for the high benzoate period, to 14.9 grams;

for the after period, to 13.6 grams. It should be noted that the nitrogen excretion during the fore period was rather high as compared with that of the other subjects, especially if we consider them from the standpoint of their weights.

# NITROGEN BALANCE.

The data relating to the nitrogen balance in this case are given in table Series F, IV L. They show for the fore period an average daily negative balance (i. e., a lesser nitrogen intake than output) of 1.56 grams, for the low benzoate period a negative balance of 2.14 grams, for the high benzoate period a negative balance of 1.99 grams, for the after period a positive balance of 1.42 grams.

The daily nitrogen intake with the food was as follows:

		rams.
Fore period		16. 00
High benzoate period	1	17. 06
After period		16. 74

There is no evidence, derivable from data given in this table that there was any disturbance in nitrogenous metabolism during any of the periods of the experiment.

## NITROGEN OF UREA.

We may consider the nitrogen of urea from the standpoint of percentages of total nitrogen (Series D, IV L). We find for the fore period an average of 86.8 per cent; for the low benzoate period, 82.8 per cent; for the high benzoate period, 84.1 per cent; for the after period, 83.5 per cent. These variations being within the limits of the normal, and being in themselves slight, call for no comment.

## NITROGEN OF AMMONIA.

The daily average excretion of nitrogen of ammonia was 0.70 gram for the fore period (Series B, IV L), 0.59 gram for the low benzoate period, 0.52 gram for the high benzoate period, and 0.55 gram for the after period. Looking at the nitrogen of ammonia from the standpoint of percentages (Series D, IV L), we find that for the fore period the ammonia nitrogen amounted to 4.2 per cent of the total nitrogen; for the low benzoate period to 4.3 per cent; for the high benzoate period to 3.5 per cent; and for the after period to 4 per cent. The variations in percentages between the different periods are slight and unimportant.

#### TOTAL PURIN NITROGEN.

Considering the daily average purin nitrogen, we find that this amounted to 0.28 gram for the fore period (Series B, IV L), 0.26 gram for the low benzoate period, 0.27 gram for the high benzoate period,

and 0.25 gram for the after period. These figures indicate a close uniformity in the purin nitrogen excretion throughout the different periods. Considering these values from the standpoint of percentages (Series D, IV L), we find that for the fore period the average purin nitrogen was 1.6 per cent of the total nitrogen; for the low benzoate period, 1.9 per cent; for the high benzoate period, 1.8 per cent; for the after period, 1.9 per cent. These slight variations can not be regarded as other than wholly insignificant in connection with the present investigation.

## NITROGEN OF URIC ACID.

The average daily excretion of uric acid nitrogen for the fore period was 0.22 gram (Series B, IV L); for the low benzoate period, 0.22 gram; for the high benzoate period, 0.23 gram; and for the after period, 0.21 gram. Looked at from the standpoint of percentages (Series D, IV L), we find only slight and insignificant variations for the different periods, since the average uric acid nitrogen for the fore period was 1.3 per cent of the total nitrogen; for the low benzoate period, 1.6 per cent; for the high benzoate period, 1.5 per cent; for the after period, 1.5 per cent.

### NITROGEN OF CREATININ.

The daily average output of creatinin nitrogen for the fore period was 0.46 gram (Series B, IV L); for the low benzoate period, 0.59 gram; for the high benzoate period, 0.69 gram; for the after period, 0.66 gram. The distinct rise in nitrogen of creatinin during the benzoate periods is noteworthy, inasmuch as it is a concomitant of the fall in total nitrogen. The rise in nitrogen of creatinin is even more noteworthy when we look at it from the standpoint of percentages (Series D, IV L), for we see that while for the fore period the average was 2.8 per cent of the total nitrogen, it was 4.3 per cent for the low benzoate period, 4.6 per cent for the high benzoate period, and 4.9 per cent for the after period. A reference to the table of caloric values of the food (Series H, IV L) shows that the average daily intake of protein for the low benzoate period (85.1 grams) was less than that for the fore period (100 grams). On the other hand, the protein intake for the high benzoate period was greater (106.8 grams daily) than during either of the preceding periods. While there is thus no definite ratio between the creatinin excretion and the total protein intake, it is likely that the explanation in the creatinin fluctuations is to be found in the variations in the quantity of meat ingested.

## NITROGEN OF HIPPURIC ACID.

The nitrogen of hippuric acid is best considered in connection with Table IV L, Series E. From this table we see that the average daily amount of benzoic acid ingested, calculated from the sodium

benzoate, amounted to 0.2541 gram for the low benzoate period; we see also that the benzoic acid excreted during this period, and attributable to the benzoic acid intake, amounted to 0.1858 gram. For the high benzoate period the benzoic acid intake was 1.5730 grams, and the calculated amount excreted attributable to this intake amounted to 1.4295 grams.

## UNDETERMINED NITROGEN.

The average daily output of undetermined nitrogen for the fore period was 0.76 gram (Series B, IV L); for the low benzoate period, 0.82 gram; for the high benzoate period, 0.63 gram; for the after period, 0.67 gram. The variations are here too small to call for comment. The average percentage of the undetermined nitrogen for the fore period was 4.2 per cent of the total nitrogen; for the low benzoate period, 6 per cent; for the high benzoate period, 4.1 per cent; for the after period, 5 per cent.

### TOTAL SULPHUR.

The average daily total excretion of sulphur for the fore period was 1.253 grams (Series B, IV L); for the low benzoate period, 1.024 grams; for the high benzoate period, 1.101 grams; for the after period, 0.977 gram. The variations here are inconsiderable.

#### INORGANIC SULPHUR.

The daily average output of inorganic sulphur for the fore period was 1.035 grams (Series B, IV L); for the low benzoate period, 0.814 gram; for the high benzoate period, 0.879 gram; for the after period, 0.789 gram. We note here a fall similar to that observed for the total sulphur. Considering the inorganic sulphur in percentages of total sulphur (Series D, IV L), we see that the variations of the averages from period to period are unimportant, being 82.7 per cent for the fore period, 79.5 per cent for the low benzoate period, 79.8 per cent for the high benzoate period, and 80.7 per cent for the after period.

## ETHEREAL SULPHUR.

The average daily excretion of ethereal sulphur for the fore period was 0.053 gram (Series B, IV L); for the low benzoate period, 0.055 gram; for the high benzoate period, 0.058 gram; for the after period, 0.048 gram. The variations here are small and insignificant. In the fore period the average ratio between inorganic and ethereal sulphur was 19.7 (Series D, IV L); in the low benzoate period, 14.7; in the high benzoate period, 15.1; in the after period, 17.1. These changes are so small and fall so well within physiological limits that no significance can properly be attached to them.

#### NEUTRAL SULPHUR

The average daily output of neutral sulphur amounted to 0.165 gram for the fore period (Series B, IV L). 0.155 gram for the low benzoate period, 0.164 gram for the high benzoate period, and 0.140 gram for the after period. Looking at the neutral sulphur from the standpoint of its percentage of the total sulphur we find that during the fore period the average was 13.1 per cent; for the low benzoate period, 15.1 per cent; for the high benzoate period, 14.9 per cent; for the after period, 14.4 per cent. These variations are small and fall well within the variations observed under strictly physiological conditions and they therefore call for no comment.

#### PHOSPHATE PHOSPHORUS.

The average daily phosphorus in the form of phosphates of the urine for the fore period was 1.51 grams (Series B, IV L); for the low benzoate period, 1.2 grams; for the high benzoate period, 1.28 grams; for the after period, 1.09 grams. These fluctuations are within normal limits.

### INDICAN.

There was in this case a slight rise in the intensity of the indican reactions of the urine during the high benzoate period (Series A, IV L). As the protein intake for this period was somewhat higher than for any other period, the rise in the indican is possibly attributable to increased intestinal putrefaction due to this cause, but the possibility remains that the increased intensity of the reactions was dependent on the high dosage with sodium benzoate.

### INDOLACETIC ACID.

Frequent examinations were made for the presence of indolacetic acid. It was found to be present at all times. The reactions were commonly slight, sometimes moderately strong. There was no evidence that the color reactions for indolacetic acid in the urine were in any way influenced by the ingestion of sodium benzoate.

### AROMATIC OXYACIDS.

Frequent examinations were made for the presence of aromatic oxyacids. Color reactions were obtainable at all times during the experiment. The reactions were commonly slight, sometimes moderately strong. There was no evidence that the color reactions for aromatic oxyacids in the urine were in any way influenced by the ingestion of sodium benzoate.

## CHLORINE AS SODIUM CHLORIDE.

The average daily chlorine excretion calculated as sodium chloride was 11.6 grams for the fore period (Series B, IV L), 11.1 grams for

the low benzoate period, 11.5 grams for the high benzoate period, and 11.9 grams for the after period. There is thus great uniformity for the different periods.

THE FECES.

FRESH.

The daily average weight of the fresh feces for the fore period was 211.9 grams (Series B, IV L); for the low benzoate period, 154.2 grams; for the high benzoate period, 138.9 grams; and for the after period, 138.5 grams.

DRIED.

The daily average weight of the dried feces for the fore period was 34.4 grams (Series B, IV L); for the low benzoate period, 28.9 grams; for the high benzoate period, 26.5 grams; and for the after period, 25.6 grams.

WATER.

The percentage of water in the fresh feces was nearly the same in the different periods (83.7, 81.3, 81.7, 81.2 per cent, Series D, IV L); in other words, the weights of the moist feces were very nearly proportional to the solids.

TOTAL NITROGEN.

The average total nitrogen of the dried feces for the fore period amounted to 1.81 per cent (Series F. IV L); for the low benzoate period to 1.59 per cent; for the high benzoate period to 1.63 per cent; for the after period to 1.47 per cent. These variations are seen to follow rather closely the variations of the intake of nitrogen with the food.

ETHEREAL EXTRACT.

The average daily weights of the ethereal extracts of the dried feces including the fatty acids of the soaps for the various periods were as follows (Series G, IV L): For the fore period, 6.45 grams; for the low benzoate period, 5.09 grams; for the high benzoate period, 4.60 grams; for the after period, 3.73 grams.

## FAT BALANCE.

In this case (Series G, IV L) the daily average intake of fat varies rather widely in the different periods, e. g., from 79.5 grams for the low benzoate period to 122.6 grams in the high benzoate period.

The fat of the feces shows only moderate variations for the different periods in respect to the percentage of neutral fats, free fatty acids, and fatty acids of soaps. The figures for these various forms of fat all lie within the limits of the normal. There is no evidence that either small or large doses of sodium benzoate exerted any influence on the percentage of neutral fats, fatty acids, or soaps appearing in the feces.

The data bearing on the absorption of fat from the intestine show nothing worthy of special comment. The proportion of fat absorbed in the different periods varies somewhat more widely than in the other cases. Nevertheless the variations are small and fail to give any evidence that either the small or large doses of benzoate exerted any influence on the fat absorption. The percentage of fat absorbed during the different subperiods is as follows:

,	Per cent.
Fore period (II)	95. 5
Low benzoate period (VII)	92. 6
Low benzoate period (X)	94. 5
High benzoate period (XIII)	95. 8
High benzoate period (XV)	96. 4
After period (XVII)	95.6

## GENERAL URINARY EXAMINATION.

### ALBUMIN.

At no time in the course of the experiment could albumin be detected in the urine, even in traces. Examinations were made with frequency and regularity.

#### SUGAR.

At no time in the course of the experiment could sugar be detected in the urine. Examinations were made frequently and regularly.

#### SEDIMENTS.

Calcium oxalate and phosphates were frequently observed as urinary sediments, but no more often during the benzoate periods than during the fore period and the after period. Epithelial cells were seldom abundant and urates were rare. Casts were not observed.

The urines were well preserved in a cool place, were examined within twenty-four hours after being passed, and were subjected to frequent and regular microscopical examinations.

## SPECIAL URINARY EXAMINATION FOR BENZOIC ACID.

During the high benzoate period the urine was subjected to chemical procedures designed to detect the presence of benzoic acid or benzoates. It was impossible to detect the presence of benzoic acid in the urine.

## SPECIAL CHEMICAL EXAMINATION OF THE FECES.

The data relating to the feces and comprised under the above title pertain to the reactions, the color, the consistence, the mercuric chloride reaction for hydrobilirubin, the p-dimethylamido-benzalde-hyde reaction for indol and skatol, and the quantitative determination of hydrogen sulphide.

The reaction of the feces was usually alkaline to litinus, very seldom acid. The reaction does not appear to have been influenced by the ingestion of sodium benzoate.

The color of the feces was usually brown, often yellow or yellow-brown, sometimes black from lampblack or charcoal used for demarcation. The color of the feces appears to have been uninfluenced by the taking of the sodium benzoate.

The consistence of the feces varied usually within normal limits but with a distinct tendency to soft movements with occasional diarrhea.<sup>a</sup> It does not appear that the consistency of the feces was influenced by the ingestion of sodium benzoate, since the consistency of the feces was not diminished during the high benzoate period as compared with the after periods.

The reaction for hydrobilirubin was very variable, being sometimes slight, sometimes moderate, sometimes strong or very strong. It does not appear to have been influenced by the use of sodium benzoate. It may be mentioned that in studies on this subject made independently of the present investigation, and some time previously, a distinct tendency was noted toward the development of strong hydrobilirubin reactions.

The reaction for indol was usually slight or moderate. The reactions are perhaps a little stronger in the high benzoate period than in the remaining periods. All these reactions are, however, well within the limits observed in persons in what is considered the best of health. The color reactions frequently showed the blue tint pointing to the presence of skatol. This peculiarity had been noticed in this subject during a long period of study prior to the present investigation. It is not connected, therefore, with the ingestion of sodium benzoate.

## HYDROGEN SULPHIDE.

Quantitative determinations were made of the hydrogen sulphide of the feces from September 5 to the end of the experiment (see Series I, IV L). The figures obtained in the present instance fall well within the limits of the normal. They indicate only small percentages of hydrogen sulphide, both in the high benzoate period and in the after period. We are thus justified in concluding that the fixation of hydrogen sulphide in the feces of this subject was not influenced by the use of large doses of sodium benzoate.

NOTE.—In addition to this chemical examination, the feces were subjected to microscopic study to determine whether there were any alterations in their character indicating a diminished absorption of foodstuffs (e. g., meat fiber, fats, etc.) during the benzoate periods.

<sup>&</sup>lt;sup>a</sup> The daily variations in the water content of the feces may be found in the tables relating to Case IV in Series A.

No changes of this character were detectable. Moreover, no increase in mucus was observable and no increase in cellular elements (including leucocytes) derived from the intestinal wall.

## BACTERIOLOGICAL EXAMINATION OF THE FECES.

The bacteriological examination of the feces in this case was carried on along the same lines as already mentioned in the cases already discussed. Both the direct examination of the feces and the study of the fermentation tube sediments showed the presence of considerable numbers of cocci. This peculiarity was noted throughout the benzoate experiment, but was somewhat emphasized about the time of the high benzoate period. As, however, this same peculiarity has been noticed in a large number of examinations made in the year preceding the dosage with benzoate, it can be attributed to conditions wholly distinct from the examination itself. The only possibility of an influence on the coccal forms of the feces, exerted by the benzoate, relates to the high benzoate period. It is possible that the moderate increase in coccal forms, noted at this time, was brought about by the rather large doses of sodium benzoate. No other alterations in bacterial types was observable by the methods employed in the investigation.

As will be seen by reference to Series K, IV L, there was observed the smallest gas formation by the fecal flora at the time of the high benzoate dosage. It is probable that the somewhat prolonged tendency to low gas formation, noted at this time, was at least in a measure attributable to the rise in the dose of sodium benzoate.

# CALORIC VALUES OF THE FOODSTUFFS.

The daily average for the caloric value of the food ingested was as follows (Series H, IV L):

	Calories.
For the fore period	2, 411
For the low benzoate period	
For the high benzoate period	2, 982
For the after period	2.567

These calorific values were adequate but not excessive for a man not much above the average weight, leading an indoor life and moderately active in muscular exercise.

### SPECIAL CLINICAL DATA.

#### WEIGHT.

The variations in weight in Case IV L are readily seen from the inspection of Series J, IV L, where they are graphically represented.

The weight of the subject showed a fall from about 68 kilograms to about 66 kilograms before the low benzoate period was begun. The

occurrence of digestive disorder in this subject has already been mentioned. There was a slight tendency to a rise in weight during the high benzoate period, despite some digestive disorder. (See also Series A. IV L.)

## EXAMINATION OF THE BLOOD.

#### HEMOGLOBIN.

The curve for hemoglobin (Series L, Chart IV) shows a slight tendency to rise during the high benzoate period. There is no evidence that the benzoate has had any deleterious influence on the hemoglobin.

# RED BLOOD CELLS.

The curve representative of the numbers of the red blood cells shows a slight tendency to rise during the high benzoate period. There is no reason to suppose that the ingestion of benzoate has had any unfavorable influence on the red blood cells. (Series L, Chart III.)

## WHITE BLOOD CELLS.

The white blood cell curve shows only unimportant irregularities, which can not be connected with the ingestion of sodium benzoate. (Series L, Chart III.)

The differential leucocyte count shows variations only within the physiological limits. (Series L, Charts I and II.)

# FREE HYDROCHLORIC ACID.

The curve showing the free hydrochloric acid of the gastric juice shows a rather marked rise during the high benzoate period. As a comparable rise is evident in all the other subjects, we are disposed to connect it with the ingestion of sodium benzoate. (Series L, Charts III and IV.)

### SUMMARY OF CONCLUSIONS RELATIVE TO CASE IV L.

In stating the conclusions derivable from this investigation relative to the action of sodium benzoate on the human body it is necessary to distinguish between the effects of small doses (under 0.5 gram daily) and the effects of large doses (over 0.5 gram daily).

# ACTION OF SMALL DOSES OF SODIUM BENZOATE.

It may be stated that no action from small doses of sodium benzoate was detectable by the methods employed in this investigation in respect to the following features:

(1) The general health of the subject as indicated by the subjective and objective signs.

(2) The composition of the urine (with one exception, viz, the physiological effect on the hippuric acid excretion).

(3) The composition of the feces.

(4) The absorption of fats and the fat balance.

(5) The character of the bacteria of the intestinal tract.
(6) The weight of the body.
(7) The hemoglobin of the blood.

(8) The red blood cells. (9) The white blood cells.

The observed rise in hippuric acid of the urine was such as was to be expected from the well-known metabolism of benzoic acid in the animal organism.

# ACTION OF LARGE DOSES OF SODIUM BENZOATE.

It may be stated that no definite physiological consequences of large doses of sodium benzoate were detectable by the methods employed in this investigation, except in the following respects:

(1) There was a considerable or large rise in the hippuric acid excretion, such as would be expected from the doses of sodium ben-

zoate ingested.

- (2) There was an increase of the indican of the urine, not great but unmistakable. This rise is possibly attributable to an action of the sodium benzoate (perhaps a slight irritant action in the gastro-enteric tract), so altering the secretions and bacteria as to favor intestinal putrefaction. The behavior of the ethereal sulphates indicates that the rise in intestinal putrefaction is slight.
- (3) There was a depression of the gas-producing function of the mixed fecal bacteria in dextrose bouillon.
- (4) There was a moderate but apparently unmistakable rise in the proportion of coccal bacteria observed in the fermentation tube sediments derived from the inoculation of the mixed fecal flora.
- (5) There was a distinct rise in the free hydrochloric acid of the gastric juice.

# SUMMARY OF CONCLUSIONS RELATIVE TO THE GROUP OF PER-SONS (FOUR CASES) ON WHICH THIS INVESTIGATION IS BASED.

In stating the general conclusions relative to the action of sodium benzoate on the human body it is necessary to distinguish between the effect of small doses (under 0.5 gram daily) and the effect of large doses (over 0.5 gram daily).

# ACTION OF SMALL DOSES OF SODIUM BENZOATE

The following general conclusion may be drawn: No action from small doses of sodium benzoate was detectable by the methods used in this investigation in respect to the following physiological features:

(1) The general health of the subject as indicated by subjective and objective signs.

(2) The composition of the urine (with one exception, viz, the physiological effect on the hippuric acid excretion).

(3) The composition of the feces.

(4) The absorption of fats and the fat balance.

(5) The character of the bacteria of the intestinal tract.

(6) The weight of the body.
(7) The hemoglobin of the blood.

(8) The red blood cells. (9) The white blood cells.

The observed rise in hippuric acid of the urine was such as was to be expected from the well-known metabolism of benzoic acid in the animal organism.

The methods used in this investigation are confidently believed to be sufficiently varied in scope and sufficiently searching in their specific qualities to have revealed significant modifications of normal physiological processes had such modifications been induced by the use of small doses of sodium benzoate.

The only noteworthy modification of a physiological process which was detected was the rise in the excretion of hippuric acid. This rise can not be regarded as having any pathological significance, since it falls well within physiological limits of function, such as are observable after the free use of natural food (e.g., certain fruits and berries) rich in benzoic acid. Moreover, there is no evidence that the process of synthesis of benzoic acid and glycocoll to hippuric acid entails any direct or indirect effects of a detrimental nature on any part of the human organism, even when the quantity of benzoic acid ingested is larger than that employed in our "low benzoate" period, or indeed in our "high benzoate" period. And, finally, there is no reason to suppose that the synthesis and excretion of hippuric acid in the amounts observed in our "low benzoate" experiments has any injurious effect on the organism even when excretion in such amounts is prolonged for months or years.

The failure to detect significant departures from any physiological processes may safely be taken as a practical certainty that none of the experimental subjects who submitted themselves to our investigation derived any injurious effects therefrom. The fact that the composite curves made from our subjects to indicate the body weight and the hemoglobin percentage show a rise both in weight and in hemoglobin for the entire benzoate experiment (low benzoate period and high benzoate period) is a practical and obvious confirmation of this conclusion derived from two important indices of physiological well being or health.

### ACTION OF LARGE DOSES OF SODIUM BENZOATE.

It may be stated that no definite physiological consequences of large doses of sodium benzoate were detectable by the methods employed in this investigation except in the following instances:

- (1) There was a considerable or large rise in the hippuric acid excretion, such as would be expected from the doses of sodium benzoate ingested. The significance of this rise has been discussed at sufficient length in the preceding section dealing with small doses of sodium benzoate.
- (2) There was an increase of the indican of the urine, not great but unmistakable. This rise, discernible in all four subjects, seems attributable to an action of the sodium benzoate, as other known factors in the experimental conditions fail to satisfactorily account for it. It is perhaps attributable to a slight irritant action on the gastroenteric tract, so altering the secretions or bacteria (or both) as to favor intestinal putrefaction.
- (3) There was a depression of the gas-forming function of the mixed fecal bacteria.
- (4) There was a moderate but apparently unmistakable rise in the proportion of coccal bacteria observed in the fermentation tube sediment derived from the inoculation of the mixed fecal flora. The precise significance of this phenomenon and of the depression in gas production noted in paragraph (3) is not known, but both conditions are frequently associated with slight or pronounced inflammatory affections of the gastro-enteric tract.
- (5) There was a distinct rise in the free hydrochloric acid of the gastric juice. In relation to this feature, Dr. J. S. Thacher makes the following comments:

On reviewing the findings, one result appears rather striking, the marked and, after the first few weeks, fairly continuous increase in the amount of free hydrochloric acid. The observations which I have included among the charts showing the effect of the addition of benzoate of soda to specimens of gastric contents demonstrated, as was to be expected, that the direct effect of such addition is to diminish the amount of free hydrochloric acid. The low figures for free hydrochloric acid in the early weeks and their later increase might possibly be accounted for in part by the nervous disturbance associated with the unaccustomed procedure of gastric expression and the later diminution of this disturbance as the subject became accustomed to the procedure, but I do not believe that this can account for the great and steady increase in the amounts of free hydrochloric acid. (Excerpt from letter of Dr. J. S. Thacher, dated December 16, 1908.)

If it were necessary to give an opinion as to the cause of the deviations, for the most part slight deviations, from physiological functions, which should account for the phenomena noted in paragraphs 2, 3, 4, and 5, we would offer the hypothesis that the phenomena in question are best accounted for on the supposition that the gastroenteric muscosa in some part of its course had been subjected to slight stimulant or irritative action and that this action was exerted by the continued use of rather large doses of sodium benzoate.

#### METHODS.

#### URINE.

#### PRELIMINARY PROCEDURE.

Each 24-hour sample was collected in a bottle containing 5 c. c. of a 10 per cent solution of thymol in chloroform. The samples during collection and during the period of analysis were kept as much as possible in a refrigerator.<sup>a</sup>

With few exceptions, the urines were collected for periods of 48 and 72 hours. All analyses were made in duplicates on a uniform sample covering the period of collection. The results recorded are uniformly based on a volume representing a 24-hour collection. When the period of collection was 48 hours or longer, the results recorded represent the average for 24 hours.

# TOTAL NITROGEN.

The total nitrogen was estimated according to the Kjeldahl method by digesting 5 c. c. of the urine with 20 c. c. concentrated sulphuric acid, a small quantity of copper sulphate and 10 grams of potassium sulphate; distilling alkaline with sodium hydroxide into quarter normal hydrochloric acid; titrating with quarter normal ammonia, using a few drops of an alcoholic solution of alizarin as indicator.

### UREA NITROGEN.

The urea nitrogen was estimated according to the method of Folin (American Journal of Physiology, Vol. XIII, p. 45, 1905), digesting one and one-half to two hours, and distilling in somewhat more strongly alkaline solution.

<sup>a</sup> To test the question of decomposition the ammonia of a given urine thus treated was estimated by Folin's method on successive dates. The following table shows the titrations of the excess of acid, having used the same amount for each determination, with the quarter normal NH<sub>4</sub>OH solution:

1	June 17.	June 18.	June 19.	June 20.	June 22.
II	c. c. 3. 85 4. 0	c. c. 3. 85 3. 90	c. c. 3. 90 3. 90	c. c. 3. 95	c. c. 4. 0

In regard to the use of chloroform as possibly affecting the chlorine estimation portions of a freshly voided sample of urine gave in titration, 3.95 c. c. and 3.95 c. c., NH<sub>4</sub>CNS solution; portions of the same sample treated with chloroform gave after two days, 3.95 c. c. and 4 c. c. NH<sub>4</sub>CNS solution; after five days the titration with NH<sub>4</sub>CNS solution amounted to 3.9 c. c. and 4 c. c. The decomposition of chloroform, under the prevailing conditions, with liberation of hydrochloric acid, is therefore a slow one and not of importance in the present investigation.

AMMONIA NITROGEN.

According to Folin (loc. cit.).

## TOTAL PURIN NITROGEN.

The uric acid nitrogen was estimated according to the method of Folin (loc. cit.) and the remaining purin nitrogen according to the method of Krüger and Schmidt (Zeitschrift für physiologische Chemie, Band XLV, p. 1, 1905), by precipitating the total purin bodies with sodium bisulphite and copper sulphate solutions, decomposing with sodium sulphide, oxidizing the uric acid with manganese dioxide, precipitating the remaining purin bodies with sodium bisulphite and copper sulphate solutions, and estimating the nitrogen of the precipitate by the Kjeldahl method, using tenth normal acid and alkali and alizarin as indicator.

URIC ACID NITROGEN.

According to Folin (loc. cit.).

CREATININ NITROGEN.

According to Folin (loc. cit.).

## HIPPURIC ACID NITROGEN.

To 100 c. c. of urine evaporated practically to dryness on the water bath are added 1.0 gram of acid sodium phosphate, NaH<sub>2</sub>PO<sub>4</sub>, and about 15 grams of calcium sulphate (gypsum). The finely powdered mass after being thoroughly dried in the oven is transferred to an extraction thimble, and extracted 2 hours with a rapid flow of ethyl acetate in a Soxhlet extractor. The ethyl acetate extract measuring about 100 c. c., completely transferred to a separating funnel, is washed by shaking vigorously with four successive portions of 10 c. c. saturated sodium chloride solution. The washed ethyl acetate solution is transferred to a Kjeldahl flask, 25 c. c. of water are added, the ethyl acetate removed by distillation, and the nitrogen of the hippuric acid residue determined by the Kjeldahl method, using tenth normal acid and alkali, and alizarin as indicator.

#### UNDETERMINED NITROGEN.

The undetermined nitrogen represents the difference between the total nitrogen and the sum of the nitrogen of the following bodies: Urea, ammonia, purin, creatinin, and hippuric acid.

#### TOTAL SULPHUR.

Ten cubic centimeters of urine are completely oxidized in a 300 c. c. Kjeldahl flask with 15 c. c. fuming nitric acid according to the method of Schulz (Pflüger's Archiv., vol. 121, p. 114). The total

sulphur in the ash, after dissolving in dilute hydrochloric acid and diluting, is determined according to Folin's method (Journal of Biological Chemistry, vol. 1, p. 131, 1906).

INORGANIC SULPHUR.

According to Folin (loc. cit.).

ETHEREAL SULPHUR.

According to Folin (loc. cit.).

NEUTRAL SULPHUR.

The neutral sulphur was estimated by subtracting the sum of the inorganic and ethereal sulphur from the total sulphur.

# PHOSPHATE PHOSPHORUS.

The phosphorus was estimated according to the method described in Neubauer und Vogel's Analyse des Harns, 1890, page 730, by titrating with uranium nitrate in the presence of sodium acetate and acetic acid, using cochineal as indicator.

INDICAN.

According to Folin (American Journal of Physiology, Vol. XIII, p. 45, 1905).

CHLORINE AS SODIUM CHLORIDE.

Volhard's method (Neubauer und Vogel, Analyse des Harns, 1890, p. 705).

#### ALBUMIN.

The tests employed for the detection of albumin were as follows: The heat test, made by heating a portion of the clear urine with a drop of nitric acid, also by treating the hot clear urine with a drop of trichloracetic acid in a darkened room holding the test tube before a highly illuminated slit; the contact test, made by bringing the clear urine in contact with nitric acid and also with trichloracetic acid without mixing.

SUGAR.

The presence of reducing substances in the urine was tested for by heating the urine with Fehling's solution.

#### FECES.

The periods during which the feces were collected conformed to the urinary periods and food periods, and were ascertained by marking with lampblack.

#### WATER.

The feces of one day were intimately mixed and divided into three equal portions. One portion, slightly acidified with sulphuric acid and evaporated to dryness on the water bath and dried in the oven, was used for the estimation of total nitrogen and, incidentally, of water. A second unacidified portion was likewise evaporated to dryness and used for the estimation of total ether extract, including neutral fats, free fatty acids, and the fatty acids of soaps, and also water. The percentage of water of fresh feces recorded in the tables is the average of these two estimations on each sample. The third portion was used for qualitative tests, including hydrobilirubin and indol, for the quantitative estimation of hydrogen sulphide, and for the bacteriological examination.

### TOTAL NITROGEN.

Aliquot portions, usually one-tenth, of the finely divided, dried feces from the acidified samples collected during a given period were weighed out and added together. Duplicate analyses for total nitrogen were made on the intimately mixed samples thus obtained by the Kjeldahl method, digesting with concentrated sulphuric acid, copper sulphate, and potassium sulphate.

TOTAL ETHER EXTRACT, NEUTRAL FATS, AND FREE FATTY ACIDS.

Representative samples from aliquot portions of the nonacidified dried feces for the given periods were likewise obtained, and the method employed for the estimation of the total ether extract, including neutral fats, free fatty acids, and fatty acids of soaps, was essentially that described by F. Müller (Zeitschr. f. klinische Medicin, vol. 12, p. 45, 1887), and was as follows:

Two grams of finely divided and thoroughly dried feces were extracted in a Soxhlet condenser 18 to 20 hours with Kahlbaum's low-boiling petroleum ether. The ether extract, representing the neutral fats and free fatty acids, was thoroughly dried and weighed. This extract was then dissolved in petroleum ether and alcohol and the free fatty acids estimated by titrating with a standard solution of potassium hydroxide in alcohol, using phenolphthalein as indicator. The free fatty acids thus measured were calculated as stearic acid.

The contents of the extraction thimble, containing the soaps, were treated with a dilute solution of hydrochloric acid and evaporated to dryness. The finely divided and thoroughly dried residue was extracted with petroleum ether as before, and the dried extract representing the fatty acids of the soaps was weighed. This weight added to the weight of the first extract represents the weight of the total ether extract, or "total fats" recorded in the tables.

Duplicate analyses were made throughout, with the exception of those subperiods in the case of Subjects III O and IV L during which the food was not collected, when single analyses only were made.

# HYDROBILIRUBIN.

According to Schmidt (Verhandl. d. Congresses f. inn. Medicin, vol. 13, p. 320, 1895).

A few grams of the fresh feces are rubbed up in a mortar with a solution of mercuric chloride, and the presence and intensity of the reaction noted by the pink or salmon color developed on standing.

## INDOL.

Ten grams of fresh feces in 100 c. c. water acidified with sulphuric acid are distilled, and the distillate treated with a few drops of dimethylamido-benzaldehyde solution in dilute sulphuric acid, a pink coloration showing the presence of indol, a blue or violet color showing the presence of skatol.

#### HYDROGEN SULPHIDE.

A stream of air properly washed is drawn through a suspension of finely divided fresh feces in water acidulated with sulphuric acid, then through a calcium chloride tube containing cotton, and finally through a solution of lead acetate acidulated with acetic acid. The precipitated lead sulphide is filtered, dried, and weighed.

# BACTERIOLOGICAL EXAMINATION.

The methods employed are described in the section on the "Bacteriological examination of the feces" relating to Subject I R.

#### FOOD.

#### TOTAL NITROGEN.

The total nitrogen of the foods was estimated by the Kjeldahl method, oxidizing with concentrated sulphuric acid, copper sulphate, and potassium sulphate, distilling with concentrated sodium hydroxide and titrating with quarter-normal hydrochloric acid and ammonia, using alizarin as indicator.

Duplicate analyses were made throughout.

For estimating the total nitrogen of all the food material for the different periods two distinct methods were employed during the course of the experiment. For Periods I to V, inclusive, for both Subjects I R and II H nitrogen estimations on the foodstuffs for each day were made.

For all other periods for the four men, including also Period V of Subjects I R and II H, composite samples of the food material were obtained by taking aliquot portions, usually one-fifth, of each food-stuff consumed and putting it aside preserved with sodium fluoride in a jar. At the close of the period the contents of the jar were rendered uniform by being passed through a fine meat chopper and the total mass weighed without loss. Uniform samples were taken for the estimation of total nitrogen. In Period V, Subjects I R and II II, the two methods gave the following results:

	Subject I R.	Subject II H.
Total nitrogen by analysis of individual foods.  Total nitrogen of composite samples.		114. 1 111. 7

Closely agreeing results by use of the two methods are reported in Bulletin No. 117, Office of Experiment Stations, U. S. Department of Agriculture (1902), pages 42 and 43.

TOTAL ETHER EXTRACTS, NEUTRAL FATS, AND FREE FATTY ACIDS.

Portions of the composite samples were evaporated to dryness, and the finely divided and thoroughly dried residue extracted with Kahlbaum's low-boiling petroleum ether, following the same procedure as that employed on dried feces for the estimation of total ether extract, including neutral fats and free fatty acids.

## CALORIC VALUE.

In Subperiods I to V, inclusive, for Subjects I R and II H, the fuel value for the subperiods was calculated from the individual foods consumed by data obtained from Bulletin No. 28, Office of Experiment Stations, U. S. Department of Agriculture (1906). For the other periods the total weight of dried food, less the ash, was calculated from composite samples. The proteins were calculated by multiplying the nitrogen content by 6.25. The carbohydrates were considered to be represented by the residue after subtracting the proteins, ether extracts, and ash. It was assumed that 1 gram of protein as well as 1 gram of carbohydrate yields 4.1 calories, and 1 gram of fat, 9.3 calories.

#### APPENDIX.

It is essential to the completeness of this report to append the daily food charts, showing the daily intake of food. In the case of Subjects I R and II II the quantities of the various foods are given for the entire time covered by the investigation. For Subjects III O and IV L the data given relate to a part only of the experimental period. The arrangement of the data relating to the nitrogen of the food, where such data are given, is self-explanatory.

## Clinical charts.

KEY TO CHARTS.

No. I. Complete chart of all gastric and blood work.
No. II. Average of four hemoglobin estimations, six blood counts, four differentials, and two gastric analyses in each examination of patient.
No. III. Curves showing relative weights, hemoglobin, red cells, and white cells from others II.

Chart II.

No. IV. Chart, composite curves, and averages of averages of results obtained from the four test cases.

## BIBLIOGRAPHY.

Keller. Über Verwandlung der Benzoësäure in Hippursäure. Liebig's Annalen der Chemie, 1842, XLIII, 108.

Author took 2 grams of benzoic acid in evening without effect other than night sweat attributed to the acid. This dose was taken three times next day without other effects. Much hippuric acid was excreted. Urea and uric acid were not decreased.

MARCHAND. Über die Oxydationsproducte des Leims durch Chromsäure. Journal für practische Chemie, 1845, XXXV, 309.

Of 5 grams of benzoic acid taken at once most was recovered as hippuric acid. Diarrhea. During 10 days 30 grams of benzoic acid were taken. No mention of ill effects.

Wöhler and Frerichs. Über die Veränderungen, etc. Liebig's Annalen der Chemie, 1848, LXV, 335.

In experiments, mostly on dogs, benzaldehyde was transformed in the organism to benzoic acid and excreted as hippuric acid. Ethyl benzoate is transformed to hippuric acid.

KUHNE and HALLWACHS. Über die Entstehung der Hippursäure, etc. Virchow's Archiv für pathologische Anatomie, 1857, XII, 386.

Injection experiments on dogs. Formation of hippuric acid from introduced benzoic acid does not occur in intestines, nor in circulating blood, but in hepatic vessels in presence of constituents of bile (glycocholic acid).

LÜCKE. Über die Anwesenheit der Hippursäure, etc. Virchow's Archiv für pathologische Anatomie, 1860, XIX, 196.

Method of detecting hippuric acid. Many specimens of normal urine from mixed diet contain no hippuric acid. It is found after taking food mostly vegetable; also after eating fruit, especially cranberries. Fresh fruit apparently contains free benzoic acid.

LAUTEMANN. Über die Reduction der Chinasäure, etc. Liebig's Annalen der Chemie, 1863, CXXV, 9.

Author took 8 grams of the calcium salt of quinic acid, which is easily transformed into benzoic acid in the laboratory. It was excreted as hippuric acid. Same results with two other subjects.

MATTSCHEWSKY. Zur Entstehung der Hippursäure. Virchow's Archiv für pathologische Anatomie, 1863, XXVIII, 538.

In dogs, after diet of bread, meat, or milk, urine does not contain hippuric acid. Quinic and cinamic acids afford much hippuric acid. After giving benzoic acid per os, in one dog, with alkaline urine, free benzoic acid was excreted; in another, with acid urine, hippuric and benzoic acids. In man quinic acid increased the output of hippuric acid.

MEISSNER and SHEPARD. Untersuchungen über das Entstehen der Hippursäure im thierischen Organismus. Hannover, 1866.

There is no hippuric acid or benzoic acid in the blood of animals which excrete hippuric acid abundantly in the urine. According to the authors' experiments on man, ingestion of 7.6 grams of benzoic acid as sodium salt in solution after breakfast was followed suddenly, 30 minutes later, by nausea and vomiting. When 5.7 grams were taken after breakfast there was vehement vomiting after about 35 minutes. When vigorous exercise was taken after the same dose (5.7 grams) there was some nausea, but no vomiting. The nausea can be made to disappear by violent exercise, with deep inspirations, etc. After taking 3.8 grams, when the subject was kept quiet in a warm room there was no nausea or vomiting. A stronger and heavier person repeatedly took 7.6 grams without these symptoms. There was no hippuric acid in the sweat or saliva. 7.6 grams taken in two divided doses, without nausea or vomiting, failed to produce increase of urea, but rather a tendency to decrease. In man, daily outputs of hippuric acid in the urine have been observed as follows:

nave been observed as follows:	Grams.
By Weismann, on mixed diet	2. 47
By Boedeker, for normal healthy individuals	1.0 to 2.0
By Hallwachs, on diet not exclusively composed of meat	1.0
By Bence Jones	0.25 to 0.45.
By Weismann, on meat diet	0.76
By Kühne, on diet mostly of meat	Traces.
By the authors, on diet not exclusively composed of meat	0.08 to 0.1
The amount seems to be very constant under the same conditions.	

771

The authors conclude from their experiments on animals that the kidney is the only organ where benzoic acid is normally transformed into hippuric acid. When 2 grams of benzoic acid per day were fed to a rabbit during 3 days there was no decrease in usea output. In a dog of 12 to 13 kilograms, 8 grams of benzoic acid given in solution per os caused vomiting. Later 8 grams were given twice a day as dry powder packed in meat. There was apparently no decrease in usea. After several days a toxic effect was noted—difficulty in urinating, spasms, attack of rage, attempts to bite, foam at mouth. Benzoic acid was continued 2 days more and the attacks recurred. Appetite remained good. Convulsions occurred the day after the benzoic acid administration was stopped, and then they ceased. Similar attacks were observed in a small dog which received 10 grams benzoic acid for 3 days. The authors conclude that the continued administration of large amounts of benzoic acid is not without danger, although Keller took 2 grams per day for some time without feeling any ill effects. Hippuric acid is formed from benzoic acid in all animals. Authors conclude that in herbivorous animals the exerction of hipparic acid is dependent on the cuticular substance of plants ingested. The small amount in normal human urine probably derives its origin from metabolism products.

HOFMEISTER. Beobachtungen über Hippursäurebildung im Pflanzenfresserharn. Landwirtschaftliche Versuchsstationen, 1871, XIV, 458.

A study of the conditions of hippuric acid formation in herbivorous animals.

Buchholtz. Antiseptica und Bacterien. Archiv für experimentelle Pathologie und Pharmacologie, 1875, IV, 1.

Studies on the bactericidal action of benzoic acid and benzoates. Bacteria are destroyed by benzoic acid in a concentration of 1 to 250. In his media sodium benzoate inhibited development of bacteria in a concentration of 1 to 2,000; benzoic acid in a concentration of 1 to 1,000.

WEISKE. Untersuchungen über die Hippursäurebildung im Körper des Herbivoren bei Verabreichung verschiedenartiger Futtermittel. (Unter Mitwirkung von Kellner und Wienand.) Zeitschrift für Biologie, 1876, XII, 241.

The assumption of Meissner and Shepard and Harten that the cuticular substance of plants is the mother substance of hippuric or benzoic acid is little probable. A small amount of hippuric acid has a normal metabolism independent of food. In rams kept on hay, introduction of 15 grams of benzoic acid per day did not give rise to the appearance of free benzoic acid in the urine. The increase in the excretion of nitrogen after benzoic acid does not occur at the expense of urea. The urine of one animal fed with beans and potatoes was found free from hippuric acid. After addition of benzoic acid to the food (for 3 days 5 grams and for 1 day 10 grams) only free benzoic acid appeared in the urine and no hippuric acid. With same food plus glycocoll there was no hippuric acid. With glycocoll and benzoic acid and after feeding 5 grams of hippuric acid, only free benzoic acid and no hippuric acid was found in the urine. Author concludes that hippuric acid had been decomposed in the body and that the kidneys do not always form hippuric acid from benzoic acid and glycocoll.

E. Okolow. Über die Einwirkung der Salicyl- und der Benzoësäure auf Fäulniss und Gährung. Centralblatt für Chirurgie, 1876, p. 777. [Abstract by W. Grube. Original, Russian.]

Both acids inhibit putrefaction and fermentation. Benzoic acid more. Afterinternal application the urine decomposes more slowly. Small doses have no influence on stomach digestion. Large doses inhibit it completely. Small doses have no apparent influence, while larger doses decrease urea. After larger doses there is increase in amount of urine. Larger doses diminish the body weight. In 2 animals with fever benzoic acid reduced the temperature more than salicylic acid.

E. Salkowski. Zur Wirkung des benzoësäuren Natrons. Virchow's Archiv für pathologische Anatomie, 1877, LXXVIII, 53.

Author concludes that sodium benzoate causes considerable increase in the decomposition of body proteins and that it would be well not to regard the administration of large doses of benzoates during long periods as harmless medication. He found increase of nitrogen and sulphur excretion.

- A. Hoffmann. Über die Hippursäurebildung in der Niere. Archiv für experimentelle Pathologie und Pharmacologie, 1877, VII, 239.
  - Author found hippuric acid in his urine within one-hall hour after taking benzoic acid and glycocoll; neither hippuric acid nor benzoic acid in the sweat. He reports transfusion experiments with excised dog kidneys, using benzoic acid, etc. Various factors inhibit hippuric acid synthesis.
- F. Walter. Die Wirkung der Säuren auf den tierischen Organismus. Archiv für experimentelle Pathologie und Pharmacologie, 1877, VII, 148.

In a rabbit 9 grams of hippuric acid per kilogram produced no pronounced acid intoxication.

Bunge and Schmiedeberg. Über die Bildung der Hippursäure. Archiv für experimentelle Pathologie und Pharmacologie, 1877, VI, 233.

Classic description of estimation of hippuric acid and place of its formation in the animal body. In dogs hippuric acid is formed in the kidneys, which sustained their power to transform benzoic acid into hippuric acid for hours after excision.

Salkowski. Vorgang der Harnstoffbildung im Tierkörper. Zeitschrift für physiologische Chemie, 1877–1878, I, 1.

In a rabbit fed on potatoes and benzoic acid there was considerable increase in nitrogen exerction; the proportion of nitrogen to sulphur remained the same as before. The benzoic acid appeared mostly as hippuric acid. After introduction of hippuric acid the urine of rabbits reduced cupric oxide. The nature of the reducing substance is not known. Dogs take benzoic acid with their diet without injury at least for 30 days. When on 2 consecutive days between 5 and 7.5 grams of sodium benzoate were given, a definite increase in nitrogen and sulphur excretion occurred, i. e., increased protein matabolism

LAUDER BRUNTON. Text Book on Pharmacology, Therapeutics and Materia Medica. London, 1878, 3d edition, 78.

Data on the inhibitory action of benzoic acid and sodium benzoate upon various enzymes.

G. Brown. Zur Therapie der Diptheritis. Archiv für experimentelle Pathologie und Pharmacologie, 178, VIII, 140.

A 5 per cent solution of sodium benzoate seems to destroy diphtheria bacilli within one hour.

KLEBS. Über einige therapeutische Gesichtspuncte welche durch die parasitäre Theorie der Infectionskrankheiten geboten erscheinen. Prager medizinische Wochenschrift, 1878, III, 5, 16, 41, 54.

Author has often tried 5 grams of sodium benzoate on himself and others without any disturbance of digestion. In dogs the maximal permissible dose of sodium benzoate for subcutaneous injection is 1 per mille of body weight; in rabbits 2 per mille of body weight is a fatal dose.

KLEBS. Über einige therapeutische Gesichtspuncte welche durch die parasitäre Form der Infectionskrankheiten geboten erscheinen. Prager medizinische Wochenschrift, 1878, III, No. 1, 2, 5, 6.

Sodium benzoate seems to be more advantageous than salicylic acid in bacterial infections, since it can be given in larger doses without danger. Subcutaneously the maximal permissible dose is 1 per mille of body weight; 2 per mille is a fatal dose. The largest single dose to be used is 5 grams.

KLEBS. Natrium benzoicum. ('orrespondenzblatt für Schweizer Aerzte, 1878, VIII, 313.

In an oral communication to the editor the author states that there are absolutely no disagreeable effects when sodium benzoate is used for even longer periods of time, in doses up to 25 grams per day. The usual dose is 10 to 15 grams per day; the maximal dose up to 12 per mille of body weight.

Salkowski. Über den Einfluss der Verschliessung des Darmkanals, etc. Virchow's Archiv für pathologische Anatomie, 1878, LXXIII, 421.

Hippuric acid is found in the urine of the starving dog and is not increased after ligating the intestines. In rabbits hippuric acid does not appear in the urine when it is free from phenol.

E. Salkowski. Über das Vorkommen von Allantoin und Hippursäure im Hundeharn. Berichte der deutschen chemischen Gesellschaft, 1878, XI, 500.

A dog on exclusive meat diet and in hunger excretes small and varying amounts of hippuric acid. Ligating the intestines has no influence on the hippuric acid excretion.

WINTER. Zur therapeutischen Verwendung des benzoësäuren Natrons. (Abstract.) Schmidt's Jahrbücher für die gesammte Medizin, 1879, CLXXXIV, 121. Report of views of others.

NAUMANN. Über die therapeutische Verwendung des benzoësauren Natrons. (Nach Schüller, Klebs, Letzerich, Hoffmann.) Schmidt's Jahrbücher für die gesammte Medizin, 1879, CLXXXII, 125.

Discussion of the therapeutic dosage of sodium benzoate, especially in febrile processes. Dogs can endure injections of 1.7 grams per kilogram without any danger. A dog of 6.5 kilograms which received 11 grams of sodium benzoate injected within 90 minutes showed short vagus stimulation and a relatively long increase of arterial pressure. On this basis a man of 50 kilograms could withstand a dose of 85 grams of sodium benzoate. Hoffmann gives adults 10 grams per day and gave an 11-year-old girl 6 grams per day for 10 days without ill effect.

Senator. Über die Wirkung der Benzoësäure bei der rheumatischen Polyarthritis. Zeitschrift für klinische Medizin, 1879, I, 243.

The author administered sodium benzoate in doses of 4 to 6 grams per day without the slightest ill effect, then increased it to 11 to 12 grams. In acute rheumatism as much as 70 grams of sodium benzoate were given during the course of the disease, usually within 11 days, without any symptoms of irritation. Soon after administration the urine acquired strong reducing properties.

FRITSCHE. [In a discussion of a paper on inhalations of sodium benzoate in tuberculosis of the lungs.] Berliner klinische Wochenschrift, 1879, XVI, 762.

Untoward effects reported in the treatment of a tubercular patient with inhalations of sodium benzoate.

M. Schüller. Über therapeutische Versuche bei mit tuberculösen, scrophulösen, septischen Massen inficierten Tieren. Archiv für experimentelle Pathologie und Pharmacologie, 1879, XI, 84.

The author states that it is possible for an adult to take 20 to 30 grams of sodium benzoate per day internally without injurious effect.

- F. KROCZAK. Vorläufige Mitteilung über Natronbenzoicum Inhalationen am Krankenbette. Wiener medizinische Presse, 1879, XX, 1178.
- Salomon. Über den Ort der Hippursäurebildung beim Pfianzenfresser. Zeitschrift für physiologische Chemie, 1879, III, 365.

In rabbits benzoic acid or benzoic acid plus glycocoll given per os leads to the formation of hippuric acid. In herbivora the kidneys are not the only organs where this synthesis takes place, but in dogs the idea of Bunge and Schmiedeberg that the kidney is the only place of the synthesis is still valid. (Salkowski.)

Von Schröder. Über die Bildung der Hippursäure im Organismus des Schafes. Zeitschrift für physiologische Chemie, 1879, III, 323.

Author took 0.5 gram of benzoic acid in KOH, with a diet of potatoes and butter. The strongly alkaline, turbid urine contained no trace of benzoic acid. In rams fed on potatoes and beans 5 to 6 grams of benzoic acid given per os as potassium salt reappeared in urine mostly as hippuric acid (77 to 90 per cent) with relatively small amounts of free benzoic acid (4 to 23 per cent). Only small amounts of the introduced benzoate were unaccounted for. (vs. Weiske.)

R. Demme. Sechszehnter mediz. Bericht über die Thätigkeit des Jennerschen Kinderhospitals in Bern im Laufe des Jahres 1878. Schmidt's Jahrbücher für die gesammte Medizin, 1879, CLXXXIII, 218.

Diphtheria is treated with 5 to 20 grams of sodium benzoate per day, besides local treatment with it and subcutaneous injections of a 50 per cent solution in retro and submaxillary region and in the tonsils. There was no drop of temperature; the heart action was improved and urine secretion increased.

STADELMANN. Über die Umwandlung der Chinasäure in Hippursäure im Organismus der Säugetiere. Archiv für experimentelle Pathologie und Pharmacologie, 1879, X, 317.

The sodium salt of quinic acid produces an increase in hippuric acid in herbivorous animals (rabbits), but none in carnivorous animals (dogs). The output does not account for the amount of quinic acid introduced, and appears after a relatively long time.

ROKITANSKY, Zur Behandlung der Phthise mittelst Inhalationen von Natrium benzoicum. Wiener medizinische Presse, 1879, XX, 1330.

Inhalations of sodium benzoate are reported to be of great value in phthisis. A patient of 50 kilograms must use at least 50 grams in 5 per cent solution per day, the dose being determined by the body weight. Patient must inhale 1 gram per kilogram. It is assumed to reach the lung in sufficient concentration to act bactericidally.

W. Kochs. Über eine Methode zur Bestimmung der Topographie des Chemismus im tierischen Körper. Pflüger's Archiv für die gesammte Physiologie, 1879, XX, 64.

Confirmation of the Bunge-Schmiedeberg experiments on hippuric acid-formation after transfusion of dog kidney with blood plus glycocoll plus benzoic acid. The synthesis also takes place in the presence of comminuted kidney of dog, ox, and calf. Experiments with liver (dog, calf) were negative. Jaarsveld and Stokvis. Über den Einfluss von Nierenaffectionen auf die Bildung von Hippursäure. Archiv für experimentelle Pathologie und Pharmacologie, 1879, X, 268.

The urine of a healthy individual never contained free benzoic acid after administration of 0.4, 0.5.1, and 2 grams of benzoic acid within 5 days. In a patient with healthy kidneys and liver, after giving 1.5 grams benzoic acid, 60 per cent was recovered in the form of hippuric acid, 0.54 gram, and free benzoic acid, 0.34 gram. In chronic hemorrhagic pleurisy with stasis, 33 per cent of 1.2 grams of benzoic acid given was excreted as hippuric acid. There was no free benzoic acid present. In three cases of interstitial nephritis the introduced benzoic acid (maximum dose 1.5 grains) nearly always reappeared exclusively as hippuric acid. In two cases of amyloid degeneration of the kidney the introduced benzoic acid appeared, with exception of one day, only as free benzoic acid. In parenchymatous nephritis introduced benzoic acid was excreted either only as free benzoic acid or in marked preponderance as free benzoic acid; usually 50 to 60 per cent of the introduced benzoic acid reappeared. Authors conclude that benzoic acid not found in urine is not absorbed. After introduction of benzoic acid there is no increase of ethereal sulphates in the urine. Authors conclude that in man the capacity to excrete benzoic acid as hippuric acid is diminished or entirely gone in affections of the kidneys, the greatest inhibition being noted in parenchymatous nephritis. The rabbit can form hippuric acid in the small intestine and liver as well as in the kidney.

Weiske. Über Hippursäurebildung im tierischen Organismus. Zeitschrift für Biologie, 1879, XV, 618.

Author repeats experiments of feeding benzoic acid to a ram on a diet of beans and potatoes. Like Von Schröder, he now finds only hippuric acid in the urine, and no benzoic acid.

WINTER. Zur therapeutischen Verwendung der Benzoësäure und des benzoësäuren Natrons. (Abstract.) Schmidt's Jahrbücher für die gesammte Medizin, 1880, CLXXXVI, 121.

Author reports failure to observe ill effects (diarrhea) after the therapeutic use of benzoates. They are strongly diuretic.

R. Kobert. (Nach eigenen im Verein mit Dr. Schulte ausgeführten Untersuchungen.) Zur Kenntnis der Wirkung der Benzoësäure. Schmidt's Jahrbücher für die gesammte Medizin, 1880, CLXXXV, 12.

After intravenous introduction of sodium or magnesium benzoate in dogs, benzoic acid appears in the saliva. The reducing substance found in the urine after administration of benzoic acid occurs only definitely after giving extraordinarily high doses, and occasionally in persons who do not get benzoic acid. Salkowski thinks this is probably due to the benzoic acid content of the food. The presence of this substance is regarded as the first sign of intoxication. It occurs only in the urine and never in saliva. In animal experiments it was found after subcutaneous and per os administration of benzoic acid and its salts, but never after intravenous injection. In man the reducing substance did not occur in the urine after subcutaneous injection of 5 c. c. of a 30 per cent solution; it seems to be found only after administration of benzoic acid per os. In cold-blooded animals (frogs) the free acid and its salts produce the toxic effects in the same manner. These are: Clonic spasms of muscles; exceptionally tetanus; gradually vomiting, sometimes bloody, even after subcutaneous injection, respiration frequent, pulse not quickened nor retarded, except toward exitus. Reflex excitability was decreased to complete loss. Respiration stopped when reflex excitability was diminished to a very high degree, but by careful dosage restitution was still possible. The paralysis of the reflex excitability is the same after severing the brain, therefore paralysis of reflex excitability of the cord. In warm-blooded animals (rabbits, cats, dogs) toxic doses per os, subcutaneously or intravenously, produced trembling and convulsions at times, more often diminution of psychic functions; first atactic movements of the anterior extremities, paresis, then paralysis gradually progressing backward, together with a drop in temperature. In dogs there is usually vomiting, rarely diarrhea. Hemorrhages and erosions of the stomach mucosa occurred even after subcutaneous or intravenous injections. Death was due to paralysis of respiration. There seems to be a complete paralysis of brain and cord. Benzoic acid, as well as its salts, when given in doses exceeding 2 per cent (2 per mille?, see Wiener) of body weight causes in all animals intoxication followed by death. Postmortem, the mucosa of the stomach may be found hyperemic, hemorrhagic, even necrotic; therefore large doses which can only be given per os in man should be cautiously administered to avoid erosions. The appearance of reducing substance in the urine is a valuable sign of intoxication. Therapeutically, the author gave 5 to 10 grams of sodium benzoate per day. Severe toxic symptoms were avoided; but frequently very intense nausea and vomiting, sometimes with a little blood, were observed. In one case there were severe toxic symptoms, due to bleeding in the stomach. Abnormalities of pulse and blood and respiration were never seen. Larger doses, like 10 grams at one time, are not permissible on account of the stomach symptoms. Reducing substance in the urine was rarely encountered.

Weyl and Anrep. Über die Ausscheidung der Hippursäure und Benzoësäure während des Fiebers. Zeitschrift für physiologische Chemie, 1880, IV, 169.

In patients hippuric acid and free benzoic acid were found. Rabbits fed with milk and oats always excrete hippuric acid and some benzoic acid. During fever the excretion of free benzoic acid is increased and that of combined benzoic acid is decreased. The excretion of free benzoic acid could not be altered by introduction of glycocoll, suggesting that a rabbit with fever has partly lost its capacity to synthetize hippuric acid. In dogs during fever there is less hippuric acid than before, but no increase of benzoic acid. When sodium benzoate is fed to dogs in fever a much larger part of the benzoic acid reappears as free benzoic acid than in normal conditions.

E. Salkowski. Notizen. Zeitschrift für physiologische Chemie, 1880, IV, 135. Author suggests that the reducing substance found in the urine after ingestion of benzoic acid may be a glucoside-like compound.

Schmiedeberg. Über Oxydationen und Synthesen im Tierkörper. Archiv für experimentelle Pathologie und Pharmacologie, 1881, XIV, 288.

Benzoic acid may be formed from benzylalcohol and dog's blood, and in transfusion through excised kidneys. In the organism toluene is transformed to benzoic acid and hippuric acid.

Schmiedeberg. Über Spaltungen und Synthesen im Tierkörper. Archiv für experimentelle Pathologie und Pharmacologie, 1881, XIV, 379.

Author concludes that hippuric acid formation probably occurs in most or all organs of the body. A histozym capable of decomposing it also exists.

C. Virchow. Über die Einwirkung des benzoësäuren und salicylsäuren Natrons auf den Eiweissumsatz im Körper. Zeitschrift für physiologische Chemie, 1882, VI, 78.

Five to 7 grams of benzoic acid administered to dogs of 22 and 26 kilograms on successive days produced increase of nitrogen excretion; and when sodium benzoate was given to a dog in a normal state of nutrition, considerable increase of protein decomposition (25 to 40 per cent) was observed.

Salkowski. Weitere Beiträge zur Kenntnis der Harnstoffbildung. Zeitschrift für physiologische Chemie, 1882–1883, VII, 93.

In man, dog, and rabbit amido-benzoic acid is partly transformed to uramido-benzoic acid, the rest excreted partly unchanged, partly as amido-hippuric acid. Like benzoic acid, amido-benzoic acid causes increase of protein metabolism, but to a smaller extent.

J. Schiffer. Weitere Beiträge zum Verhalten des Sarkosins im tierischen Organismus. Zeitschrift für physiologische Chemie, 1882–1883, VII, 479.

In animal experiments feeding of sarkosin and benzoic acid resulted only in normal hippuric acid formation, not an excretion of sarkosin hippuric acid.

E. Salkowski and H. Salkowski. Über das Verhalten der aus dem Eiweiss durch Fäulniss entstehenden aromatischen Säuren im Tierkörper. Zeitschrift für physiologische Chemie, 1882–1883, VII, 161.

An increased output of hippuric acid was found in the urine of a dog after feeding 2 grams of phenylpropionic acid.

E. BAUMANN. Zur Kenntnis der aromatischen Substanzen des Tierkörpers. Zeitschrift für physiologische Chemie, 1883, VII, 553.

Tyrosin fed to man and dogs in large amounts never caused an increase of hippuric acid output.

Schotten. Über die Quelle der Hippursäure im Harn. Zeitschrift für physiologische Chemie, 1883, VIII, 60.

Feeding experiments on dogs with phenolamidopropionic acid, leading to the excretion of hippuric acid.

KRONECKER. Über die Hippursäurebildung beim Menschen in Krankheiten. Archiv für experimentelle Pathologie und Pharmacologie, 1883, XVI, 344.

Author maintains that a normal individual does not excrete any free benzoic acid after its introduction. After feeding 0.5 gram of sodium benzoate to 6 nephritic patients, the observations of Jaarsveld and Stokvis were confirmed in affections of the kidneys. There is a decreased capacity to transform benzoic acid to hippuric acid. In 2 cases of typhoid fever, with high temperature, nearly all of the introduced benzoic acid was excreted as hippuric acid.

Minkowski. Über Spaltungen im Tierkörper. Archiv für experimentelle Pathologie und Pharmacologie, 1883, XVII, 445.

In nephrectomized dogs the author found free benzoic acid in the blood, liver, and muscles after subcutaneous injection of hippuric acid under the necessary precautions. In rabbits the results were negative. This shows that different chemical processes go on in different chemical species. The decomposition of hippuric acid is accomplished through ferment action.

Van de Velde and Stokvis. Experimentelle Beiträge zur Frage der Hippursäurezerlegung im lebenden Organismus. Archiv für experimentelle Pathologie und Pharmacologie, 1883, XVII, 189.

Authors conclude that the existence of a ferment in the living organism leading to a decomposition of hippure acid into benzore acid and glycocoll has not yet been sufficiently proved. The contradictory results of others can be explained from the ease with which hippure acid is decomposed outside of the body in animal fluids, especially at alkaline reaction, and if they contain much athumen.

E. Salkowski. Über das Vorkommen der Phenacetursäure im Harn und die Entstehung der aromatischen Substanzen beim Herbivoren. Zeitschrift für physiologische Chemie, 1885, IX, 229.

In the horse hippuric acid may be formed from hydrocinnamic acid, a product of protein putres

faction in the intestinal tract.

E. Salkowski. Zur Kenntnis der Eiweissfäulnis III. Über die Bildung der nicht hydroxylierten aromatischen Säuren. Zeitschrift für physiologische Chemie, 1885, IX, 491.

Homologues of benzoic acid (hydrocinnamic acid and phenylacetic acid) are a constant product of protein putrefaction.

Noël Paton. On the relationship of urea formation to bile secretion. Journal of Anatomy and Physiology, 1886, XX, 114, 267.

Doses of 0.51 and 0.55 gram of sodium benzoate per kilogram in dogs have practically no influence on the amount of water excreted. The uric acid excretion is diminished, that of urea increased. The author regards sodium benzoate as an hepatic stimulant.

E. BAUMANN. Die aromatischen Verbindungen im Harne und die Darmfäulniss. Zeitschrift für physiologische Chemie, 1886, X, 123.

Author concludes that the excretion of hippuric acid in carnivorous animals (dog) is exclusively dependent on putrefactive processes in the intestines.

Baas. Über das Verhalten des Tyrosins zur Hippursäurebildung. Zeitschrift für physiologische Chemie, 1887, II, 485.

The author found no increase of hippuric acid elimination after feeding tyrosin to man.

M. Kumagawa. Über die Wirkung einiger antipyretischer Mittel auf den Eiweissumsatz im Organismus. Virchow's Archiv für pathologische Anatomie, 1888, CXIII. 134.

Metabolism experiments on dogs. An animal weighing 15 kilograms and in nitrogen equilibrium received sodium benzoate dissolved in warm water with the food as follows: First 3 days—3 grams; following 8 days—5 grams; in 11 days—41.54 grams of pure benzoic acid were given without ill effects. There was an increase of nitrogen excretion in the urine. In the last days the indican reaction was weaker. Forty per cent of the benzoic acid of the whole period was excreted as hippuric acid; 55 per cent as benzoic acid.

A dog weighing 36 kilograms and in nitrogen equilibrium received 24 grams of benzoic acid mixed in food, within 6 days; increased protein decomposition was observed. During the last days and in the after period the indican reaction was distinctly diminished, but never completely missed. The ethereal sulphates were also diminished about 20 per cent. The number of bacteria in the feces had decreased. The author concludes that benzoic acid manifests antiseptic properties in the intestines.

MOERNER. Eine Vergiftung durch Natrium benzoieum, Centralblatt für die medizinische Wissenschaften, 1888, XXVI, 545.

More than 100 grams of sodium benzoate and a little naphthalin had been introduced into a dermoid cyst of the ovary. About 30 hours later the signs of intoxication arose and the cyst was washed out. The urine contained a considerable amount of hippuric acid (1.9 grams per 100 c. c.) and gave no reduction test and no albumen. No free benzoic acid was found. In urine voided 2 days later no hippuric acid was found.

R. Cohn. Über das Auftreten von Benzamid, etc. Zeitschrift für physiologische Chemie, 1890, XIV, 202.

In dogs fed on ammonium benzoate by far the greater part is excreted as hippuric acid, with very little benzamid.

C. Binz. Vorlesungen über Pharmakologie, zweite Auflage, 1891. Berlin, Hirschwald. p. 594.

A discussion of the basis for benzoic acid therapy. Disadvantages: 6 to 8 grams of benzoic acid or sodium benzoate cause irritation of the stomach and intestine.

R. Cohn. Über das Auftreten, etc. Zeitschrift für physiologische Chemie, 1892, XVII, 310.

In rabbits and dogs benzaldehyde caused the appearance of free benzoic acid and hippuric acid, and perhaps a trace of cinnamic acid in the urine. Cinnamic acid is mostly transformed to hippuric acid.

Vogl. Realencyclopädie der gesammten Heilkunde (Eulenburg). 3 Auflage. Leipzig, 1894, III, 229.

Author reports that Schreiber took 15 grams of benzoic acid in divided doses in 2 days. The only symptoms experienced were tickling in the throat, feeling of warmth in the abdomen, and later in the whole body, and increased frequency of pulse. Next day abundant perspiration set in, increased expiration with dullness in the head, and slight transitory digestive disturbances. Author recommends 0.03 to 0.5 gram per dose as expectorant; for rheumatism, 0.5 to 1 gram every hour or every 3 hours (10 to 12 grams per day). Doses up to 25 grams of sodium benzoate per day are recommended for various conditions.

Von Jaksch. Die Vergiftungen. Specielle Pathologie und Therapie (Nothnagel), Vienna, 1897, I, 357.

Author remarks that perhaps benzoic acid and its salts are the least injurious of the whole aromatic series for the human organism; he repeatedly gave in rheumatism as high as 24 grams of sodium benzoate per dose without observing toxic effect. Cases are known where up to 60 grams per day were given. The free benzoic acid will act toxic simply as acid.

Sireci. Über die Ausscheidung der Hippursäure. Maly's Jahresbericht für Thiercliemie, 1897, XXVII, 325.

Even on a uniform diet the daily hippuric acid excretion in the same individual varies widely. Hippuric acid given internally is completely excreted as such. Even with high doses of benzoic acid it was not possible to exceed the capacity of the organism to transform all the benzoic acid to hippuric acid.

Sireci. Sulla eliminazione dell' acido hippurica. Gazetta degli Espedali e delle cliniche, 1896, XVII, 496.

Doses of benzoic acid ranging from 1 to 15 grams per day are given without noting ill effects.

Wehmer. Einige vergleichende Versuche über das antiseptische Verhalten der Benzoësäure, etc. - Chemiker Zeitung, 1897, XXI, 73; Chemisches Centralblatt, 1897, I, 548.

In concentration of 0.1 per cent benzoic acid inhibited the growth of yeast.

PFEIFFER and EBER (in Verbindungen mit Götze und MÜLLER). Beitrag zur Frage über die Bildung der Hippursäure im tierischen Organismus. Die Landwirtschaftliche Versuchstationen, 1898, XLIX, 97–144.

Protein decomposition can not be the only source of the nitrogen-free component of hippuric acid, according to experiments on the horse.

J. Pohl. Über Synthesenhemmung durch Diamine. Archiv für experimentelle Pathologie und Pharmacologie, 1898, XLI, 97.

By feeding ethylendiamin to rabbits, hippuric acid synthesis, after introduction of benzoic acid, can be markedly inhibited without any disturbance of absorption or excretion of the benzoic acid.

WIENER. Über das Glykokoll als intermediäres Stoffwechselproduct. Archiv für experimentelle Pathologie und Pharmacologie, 1898, XL, 313.

In rabbits fed with sodium benzoate it takes 4 days until all of the benzoic acid reappears in the urine, free or combined. Benzoic acid in doses of 1.7 grams per kilogram is fatal to rabbits. The values for the combined benzoic acid output are very constant, the maximum being reached with 1 gram of the acid per kilogram. When small amounts of benzoic acid are given, all of it reappears in the urine; with the large doses a constant loss occurs. Feeding of benzoic acid does not decrease the urea output. There is increase of protein decomposition, so that the total nitrogen and urea outputs are increased. When glycocoll is injected subcutaneously and benzoic acid is given per os in a fatal dose, the animal survives. Other amido acids detoxified benzoic acid similarly. The author assumes that they are transformed to glycocoll.

Kunkel. Handbuch der Toxikologie. Jena, G. Fischer, 1898, p. 550.

(1) The free benzoic acid, soluble in about 400 parts of water, when applied in powder form, has a strongly irritating action on mucous membranes, leading to strong local inflammations. Even with not very high doses, hemorrhages in the mucous membranes have been seen.

(2) Sodium benzoate appears to be very little toxic. In its application in cases of tuberculosis, doses up to 50 grams pro die were given to single individuals without ill effect, but not without action. Excessive doses cause nausea, vomiting, cullness, humming of cars, and difficulty in hearing. These symptoms disappear when the medication is stopped.

K. Serro. Über Nachweis und Vorkommen des Glykokolls. Zeitschrift für physiologische Chemie, 1899, XXVIII, 174.

Author obtained no synthesis of hippuric acid from benzole acid and glycocoil with tissue press-julee, and thinks that surviving cells are necessary.

H. LEFFMANN. Digestive ferments, with especial reference to the effect of food preservatives. Journal of the Franklin Institute, 1899, CXLVII, 97.

Benzoic acid and sodium benzoate are practically without influence on the digestive power of the enzymes studied (diastases, carase, pancreatic extracts), excepting higher concentrations. The author adds that as the preservative influence of sodium benzoate is undoubted and its disagreeable taste in any food article will prevent its liberal use it seems well adapted for general use.

- Salkowski. Über die antiseptische Wirkung von Salicylaldehyd und Benzoë-aureanhydrid. Virchow's Archiv für pathologische Anatomie, 1899, CLVII, 416. In concentration of 0.5 per cent benzoic acid anhydrid kept chopped meat mixture sterile more than 5 months; similarly 0.25 per cent. With 0.1 per cent a few colonies were grown after this time, while with 0.025 per cent the mixture showed cultures after 5 days.
- Ashhurst. Certain effects of benzoic acid upon the urine. Philadelphia Medical Journal, Feb. 24, 1900.

In dogs 1 to 2 grams of sodium benzoate administered subcutaneously for several days produced slight and inconstant diurctic effect. A dog received 1 gram of sodium benzoate daily during 2 months. No ill effects are mentioned. The author took 6 grams of sodium benzoate daily during 6 days. The quantity of urine was somewhat increased, the specific gravity slightly altered, the acidity slightly diminished.

- M. Lewandowsky. Versuche über den Einfluss der Benzoësäure auf die Harnsäurebildung. Zeitschrift für klinische Medizin, 1900, XL, 202.

A patient received 35 grams of sodium benzoate in 5 days; 15.5 grams were excreted as hippuric acid. There was no decrease of uric acid. This indicates that the formation of hippuric and uric acids are independent of each other. Three patients were fed with sodium benzoate for 2 to 7 days, and doses between 5 and 9 grams per day. In two cases a peculiar sleep-producing action of benzoic acid was noted.

The hippuric acid synthesis by kidney tissue is due to an enzyme action.

WEINTRAUD. Über den Abbau des Nucleins im Stoffwechsel. ('entralblatt für innere Medizin, 1900, XXI, 464.

An occasional increase of hippuric acid excretion after thymus feeding is due to increased intestinal putrefaction which furnishes the benzoic acid radical.

Parker and Lusk. On the maximum production of hippuric acid in rabbits.

American Journal of Physiology, 1900, III, 472.

In fasting rabbits toxic symptoms and death resulted when 1 to 0.4 gram of benzoic acid as lithium salt was given for 6 days. In fasting rabbits frequently fed with lithium benzoate the amount of glycocoll eliminated as hippuric acid compared with the total nitrogen output indicates that in metabolism the protein molecule may yield glycocoll to the extent of at least 3 to 4 per cent.

E. Curtis. Benzoic acid and Benzoates. Reference Handbook of the Medical Sciences, 1900, Vol. I.

In discussing dosage the author states that a serious derangement is scarcely possible by any likely doses of benzoic acid, intentional or accidental. In urinary disorders benzoic acid may be given several times daily in doses from 0.65 to 2 grams. Sodium benzoate has been given internally in doses amounting to 5 to 20 grams a day without serious derangement, and for pronounced therapeutic effect in rheumatism the fullest limit may be necessary. Physiologically sodium benzoate is about as harmless as a salt can be.

R. Cohn. Über den Glykokollvorrat des tierischen Organismus. Festschrift für M. Jaffé, Braunschweig, 1900 or 1901, p. 319.

Feeding with proteins, and protein decomposition products which yield glycocoll, counteracts the toxic effect of benzoic acid in rabbits.

H. Ulrici. Über pharmakologische Beeinflussung der Harnsäureausscheidung. Archiv für experimentelle Pathologie und Pharmacologie, 1901, XLVI, 321.

The author took 8 grams of sodium benzoate daily for 3 days. There was insignificant, if any, decrease of nitrogen metabolism, which the author thinks is due to the inhibiting influence of the benzoic acid on the intestinal putrefaction, so that less nitrogen is absorbed. Phosphoric acid excretion was not influenced.

  Author concludes from experiments on rabbits and sheep that the vital decomposition of protein furnishes much more glycocoll than the hydrolytic decomposition in vitro.
- H. C. Wood. Therapeutics. Principles and Practice. 12th edition. Philadelphia, 1905, p. 859.

Author states that the local action of benzoic acid, unless in large quantities, is scarcely irritant to mucous membranes, on which, however, it exerts a distinct alterative influence. The general systemic effect is very slight and the largest therapeutic doses never produce any symptom sunless they are those of slight gastric irritation. The contradictory testimony regarding the influence upon nutrition indicates that it has no constant powerful action. Doses: 0.62 gram benzoic acid; 1.3 to 3 grams of sodium benzoate.

Benzoic acid is one of the best preservatives for meat.

W. Wiechowski. Die Gesetze der Hippursäuresynthese. (Zugleich ein Beitrag zur Frage der Stellung des Glykokolls im Stoffwechsel.) Hofmeister's Beiträge zur chemischen Physiologie, 1906, VII, 204–275.

In rabbits the fatal dose of benzoic acid is about 1.7 grams per kilogram. Diarrhea next to diarresis and increase of metabolism is one of the first signs of intoxication. The benzoic acid may be excreted with the diarrheal stool. The author's experiments indicate that benzoic acid causes considerable increase of nitrogen excretion in rabbits, but not always within the first 24 hours. In rabbits hippuric acid acts like benzoic acid on metabolism. It is not harmless. Like benzoic acid it has a diuretic action and an influence on peristalsis. The total excretion of benzoic acid is not always quantitative. The loss is not constant. As a rule rabbits excrete free benzoic acid besides hippuric acid, even when small doses of benzoic acid are given, and even if glycocoll is given in amounts more than sufficient to combine with the benzoic acid. There exists no direct relation between hippuric acid synthesis and the degree of protein metabolism. Individual variations determine the extent of synthesis in the rabbit.

ABDERHALDEN and TERUUCHI. Studien über die proteolytische Wirkung, etc. Zeitschrift für physiologische Chemie, 1906, XLIX, 1.

The active press juice of dog's kidney can not decompose hippuric acid.

Brussch and Hirsch. Hippursäuresynthese und Ausscheidung der Benzoësäure beim Hunde. Zeitschrift für experimentelle Pathologie und Therapie, 1906, III, 663.

The degree of hippuric acid synthesis after introduction of benzoic acid is much lower in carnivorous than in herbivorous animals. The amount of free benzoic acid in the urine is much greater than the amount of benzoic acid paired with glycocoll. It is not possible to produce a considerable excretion of glycocoll in the dog by giving larger doses of benzoic acid, 0.8 to 1 gram per kilogram. The detoxification of benzoic acid in the dog occurs only in small part by hippuric acid formation, but mostly by formation of reducing substance. A not inconsiderable part leaves the organism as free benzoic acid. In starving dogs the benzoic acid caused a distinct increase in nitrogen metabolism and had a diuretic effect.

Author reports experiments to show that part of the hippuric acid may be synthetized in the intestine.

MAGNUS-LEVY. Über das Auftreten einer Benzoësäure-Glycuronsäure Verbindung im Hammelharn nach Benzoësäure Fütterung. Biochemische Zeitschrift, 1907, VI, 502.

Benzoylglycuronic acid is excreted after giving benzoic acid to dogs, rabbits, rams, and men. As much as 20 per cent of the introduced benzoic acid may appear in this form.

Magnus-Levy. Über die Neubildung von Glycocoll, etc. Biochemische Zeitschrift, 1907, VI, 523.

In the body more glycocoil can be produced than exists preformed in the protein decomposed. There was a definite increase in protein decomposition after larger doses of benzoic acid in a starving ram.

S. Amberg and A. Loevenhart. Further observations, etc. Journal of Biological Chemistry, 1908, IV, 149.

Sodium benzoate in concentration of 1 per cent does not inhibit the lipolytic action of clear liver extract on ethylbutyrate.

Lewinski. Über die Grenzen der Hippursäurebildung beim Menschen. Archivfür experimentelle Pathologie und Pharmacologie, 1908, LVIII, 397.

A man weighing 59 kilograms took 12 grams of benzoic acid as sodium benzoate in 12 hours on a mixed diet. He excreted no free benzoic acid and the urine contained no reducing substance. The benzoic acid was all excreted in combination. A man of 67 kilograms body weight took 20 grams of benzoic acid in 12 hours without ill effects. There was no free benzoic acid or reducing substance in the urine; but after an intake of 25 grams of benzoic acid without ill effects, 1.6 grams of free benzoic acid were excreted. When the same individual took in 8 hours 40 grams of benzoic acid in one-half hour doses, there was nausea and headache; 26 per cent of the introduced benzoic acid was excreted as free benzoic acid. The urine reduced strongly and was dextrorotatory. With a dietrich in proteins, particularly gelatine, 40 grams of benzoic acid produced no ill effects; 10 per cent of the introduced acid was excreted as free benzoic acid. The urine reduced slightly and showed slight dextro-rotation. Similarly 50 grams of benzoic acid showed no ill effects. Sixteen per cent reappeared as free benzoic acid and there was slight reduction, etc., in the urine. The author concludes that a person taking a diet rich in proteins can transform more benzoic acid to hippuric acid. The appearance of reducing substance in the urine is an expression of the impoverishment of the organism in glycocoll. In certain forms of nephritis there was a retarded elimination after ingestion of benzoic acid. In one individual 40 grams of benzoic acid and 25 grams both caused increase of nitrogen excretion. In a man of 71 kilograms on a diet poor in proteins, 30 grams of benzoic acid caused increase of nitrogen excretion and diminished uric acid output.

SEO. Über die Hippursäurespaltung durch Bacterien, etc. Archiv für experimentelle Pathologie und Pharmacologie, 1908, LVIII, 440.

Hippuric acid may readily be decomposed by bacterial action in the urine, especially when the reaction is alkaline. This may explain the conflicting results of investigators.

H. W. WILEY, with the collaboration of W. D. BIGELOW, F. C. WEBER, and others. Influence of Food Preservatives and Artificial Colors on Digestion and Health. IV. Benzoic Acid and Benzoates. United States Department of Agriculture, Bureau of Chemistry. Bulletin No. 84, Part IV, 1043-1294, 1908.

Benzoic acid and benzoate of sodium were administered in capsules in doses of 0.9 to 2.5 grams daily to healthy young men (18 in all) during successive periods of several days. The longest single period was 20 days. During one period of 10 days, doses of 1 to 1½ grams were given. The authors state that marked symptoms of discomfort and malaise were produced in the majority of cases without reference to the form in which the preservative was administered; most common symptoms were nausea and headache. The nausea resulted in vomiting in three cases. Seven

subjects complained of weakness and also of burning and irritating sensations in the esophagus; hunger was increased in three cases, and indigestion was especially noted five times. The authors assume different degrees of toleration of the substance in different individuals. A loss of weight amounting to from 0.22 kilogram to 0.46 kilogram was noted. This continued in the after period. In the original experiment the total benzoic acid recovered (as hippuric acid and as benzoic acid) amounted in the case of those receiving benzoic acid to 81 per cent of the total quantity ingested; and for those receiving sodium benzoate, to 61 per cent. In the supplemental experiment 93 per cent of the amount ingested as benzeic acid was recovered as hippuric acid, while for those receiving benzoate of soda 72 per cent was recovered. In the first series considerable benzoic acid was recovered as such from the urine. In subsequent series where the analyses were made on daily samples instead of on composites, it was mostly recovered as hippuric acid. The data on the feces are not sufficiently marked to demonstrate a distinct effect produced by the preservative. There was no diuretic effect, but an increase of the total solids exercted in the urine. A microccopic examination of the urine indicated an increase in the presence of microscopic bodiesepithelial cells, mucous strands, and mucous cylindroids—during the preservative period exemplified by the following comparative numbers for the fore, preservative, and after periods: 64, 75, 59. No significance was attached to the blood examination. While the average data did not show any marked disturbance of the nitrogen metabolism, there is a tendency to decrease the nitrogen balance. In one experiment there was an increase of 2 per cent in the preservative period of the amount of ingested nitrogen excreted in the metabolized form. The authors report indications of a tendency of the preservatives to increase the percentage of phosphoric acid excreted in the feces, and of sulphur in the feces and urine. From their data the authors conclude that either preservative "is highly objectionable and produces a very serious disturbance of the metabolic functions, attended with injury to digestion and health," such as "grave disturbances of digestion" and "distinct loss of weight." "The influence of the benzoic acid and benzoate of soda upon metabolism was never of a character indicative of a favorable change therein. While often the metabolic changes were not strongly marked, such changes as were established were of an injurious nature." "Benzoic acid and benzoate of soda are bodies which when added to foods are injurious to health."
